The slides are then placed on a mechanical shaker[7] and the rheostat set to give a rotating motion at the rate of about 120 movements to the minute. The slides are left on the shaker for thirty minutes and then taken off and placed on a table for five minutes before being read. The readings are made by naked eye and can be made by low power microscope. (The smooth surface of the plate glass permits more accurate determination of the microscopic end point of minimum agglutination than carrying out the test on slides with depressions. The end point is the observation with the low power microscope of at least three or four small clumps of not less than three or four cells. This end point must be followed by at least two squares with higher dilutions of agglutinins that are completely negative.)

6. Maximum macroscopic agglutination consisting of one or only several large clumps is called 4 plus. Lesser degrees of agglutination are 3 plus and 2 plus; 1 plus, the smallest amount of agglutination that can be detected, has a finely granular appearance and is the end point. (The next weaker agglutination is read with the low power microscope and recorded as plus minus plus [± +] and consists of many clumps made up of at least half of the cells present. Considerably smaller and fewer clumps are recorded as simply plus minus [±], and minimal clumping, consisting of at least three or four clumps of three to six cells in a low power field, is recorded as plus minus minus [± —], and in the negative tests all of the cells lie free. The end point is very sharp. Except for corroboration, microscope readings are not recommended.)

7. Boerner shaking machine number 3623, A. H. Thomas Company. The machine is made with the rheostat incorporated in the machine and under the shaking platform. The heat from the rheostat dries the tests. Therefore the rheostat should be removed and placed in the circuit some distance away from the shaker.

TEST TUBE METHOD FOR DETERMINING THE AGGLUTININ TITER

The test is carried out in a series of ¼ by 3 inch test tubes. The same dilutions of plasma are used in this test as in the large slide test.

In each test tube are placed two drops of the appropriate dilution of the plasma and two drops of 1 or 2 per cent suspension of three times washed cells. The tubes are well shaken and allowed to stand at room temperature for two hours or can be centrifuged at low speed for one minute.[8]

After gentle shaking, naked eye readings are made of the agglutination; 4 plus indicates one large clump, 3 plus when several large clumps appear on gentle shaking, 2 plus indicates many smaller clumps and 1 plus when even a few small clumps are seen or the appearance is granular and is the end point.

When microscopic examination is carried out a drop from each tube is removed with a glass rod, placed on the slide, examined under the low power of the microscope and recorded as in the large slide test.

COMMENT

Of the 1,354 pools, 134 were made of plasma from 50 individual bleedings in each pool, 850 of plasma from 25 bleedings, 355 of plasma from 6 to 10 bleedings, and 15 of plasma from 15 bleedings. The samples of pools containing 15 bleedings had been dried from the frozen state.[9] All other samples were in the original liquid state. Since the plasmas were pooled as they came to each laboratory with no selection of the blood groups of the individual plasmas, the distribution of the blood groups was by chance.

As shown in the table, of the total number of 1,354 pools in our series only 39 pools, or 2.9 per cent, showed a macroscopic anti-A titer of 1:20 or higher, and of these only 3, or 0.2 per cent, a titer of 1:40 or higher (one each 1:40, 1:60 and 1:80), none being higher than 1:80. Eighteen pools, 1.3 per cent, showed an anti-B titer of 1:20 or higher, only one as much as 1:40, and none higher than this. Therefore 97 per cent of the entire series showed both anti-A and anti-B titers less than 1:20 and 99.7 per cent less than 1:40.

From the table it can be seen that the percentage of plasmas falling into these different titration levels, regardless of the number of bleedings constituting each pool, does not show wide variation, with the exception of the group of 15 plasmas each containing 15 bleedings. Here the number examined was small, and the percentages probably cannot be compared statistically with those from the groups with the larger number of samples.

Lozner and Newhouser[3] have recently reported on the anti-A and anti-B isoagglutinin titrations of 1,000 pools of plasma. These were liquid pools containing plasma obtained from 5 to 12 donors. Some of the pools were titrated when they were 1 month old, others 1 to 4 months old, and still others over 4 months old. Our pools were titrated when comparatively fresh, about 1 month old.

They found the titer of the 4 month old pools lower than that of the pools under 4 months. Their total for the entire 1,000 pools, regardless of age, for both anti-A and anti-B agglutinins is 8.9 per cent above the titer of 1:16. Our dilutions were made in multiples of ten, and we found in 1,354 pools a total of

8. The centrifuge technic is useful when saving time is important and is to be highly recommended for cross matching transfusion tests.

9. It has been demonstrated that freezing and drying has little if any effect on agglutinin titer, except possibly to reduce it slightly.

4.2 per cent for both anti-A and anti-B agglutinins, with a titer of 1:20 or higher. Of their pools 3.3 per cent have a titer higher than 1:32, and we found only 0.28 per cent with a titer of 1:40 or higher.

Recently Blum [10] has published the agglutinin titers in forty pools containing liquid plasma from 4 to 7 donors, such as is routine in most hospital blood banks. He used Davidsohn's sensitive technic, with a low power microscope end point, and notes that these titers are higher than those with a macroscopic end point. His titers ranged from less than 1:2 to 1:56, none higher. The averages were 1:9 for anti-A and 1:22 for anti-B. These are even lower than those in Lozner and Newhouser's series.

Even with such a small percentage of pools in our series showing titers higher than 1:40, it seemed important to find out by actual trial if pools with comparatively high titers, definitely higher than the routine pools, could cause any specific reactions or harmful effects when they were administered intravenously to type A or B patients. Consequently the pool which had an anti-A titer of 1:80 was secured, and 500 cc. was administered cautiously by the intravenous route to 10 type A patients. These intravenous injections did not cause any clinical reactions or jaundice in any of the patients.

We then had prepared some pools made up entirely of 25 type O individual plasmas, so that none of the examined soon afterward under the microscope. In none were any agglutinates found.

In our series of 1,354 pools of plasma not a single pool was found with an agglutinin titer higher than 1:80. In this series there were 355 pools made up of plasma from only 6 to 10 donors. These pools are the size that are usually prepared in hospitals. We are particularly interested that in this series of small pools there was only 1 pool that had a titer of 1:40, and none higher. Therefore these small pools are just as apt to be free from high agglutinin titers as larger pools made up of from 25 to 50 individual plasmas.

Since full doses of plasma with titers varying from 1:80 to 1:256 were administered intravenously to patients of types A and B and caused no reactions, it seems clear that plasma with titers up to 1:40 certainly cannot cause incompatible reactions, and can be administered safely, regardless of the blood type of the recipient.

CONCLUSIONS

1. The anti-A and anti-B agglutinin titers were determined in 1,354 pools of human plasma.

2. The number of individual plasmas in the pools varied from 6 to 50.

3. The pools of plasma were either random samples or every fifth or tenth as they were processed routinely.

4. Of the 1,354 plasma pools, only 2 had macroscopic titers of 1:40, 1 of 1:60 and 1 of 1:80. Therefore agglutinins would be neutralized and both anti-A and anti-B agglutinins would be the highest that could possibly occur, should a pool by chance be made up entirely of type O plasma. The highest anti-A titer in these pools was 1:256 and the anti-B titer 1:128. The titers of most of the pools varied from 1:8 to 1:64. We were surprised to find the titers this low, expecting higher levels. The most probable explanation is that plasmas with low titers reduced the high titers by dilution. These results give additional confidence that small pools will have a low titer even if all or most of the individual plasmas belong to type O.

Macroscopic Readings

No. of Plasmas in Each Pool	No. of Samples	Titer 1:20 to 1:39		Titer 1:40		Titer 1:50		Titer 1:60		Titer 1:80	
		Anti-A	Anti-B	Anti-A	Anti-B	Anti-A	Anti-B	Anti-A	Anti-B	Anti-A	Anti-B
50	134	2 (1.5%)	0	0	0	0	0	0	0	0	0
25	850	22 (2.6%)	7 (0.8%)	0	0	0	0	1 (0.1%)	0	1 (0.1%)	0
6-10	355	11 (3.1%)	6 (4.5%)	1 (0.3%)	0	0	0	0	0	0	0
15	15	1 (6.6%)	4 (26.4%)	0	1 (6.6%)	0	0	0	0	0	0
Total	1,354	36 (2.7%)	17 (1.25%)	1 (0.07%)	1 (0.07%)			1 (0.07%)		1 (0.07%)	

These pools yielded about 75 500 cc. units of dried plasma. One third was sent to Capt. L. R. Newhouser (MC), U.S.N., another third to Lieut. Col. D. B. Kendrick, M. C., U. S. Army, and the other third we retained. These pools, when clinical indications arose, were injected intravenously into patients belonging to types A or B.

No patient received less than 500 cc. at one time. One patient received 500 cc. daily for four days and on the fifth day received 1,000 cc.[11] None of these patients showed any reactions, and there were no signs or symptoms of intravascular agglutination or hemolysis. In 6 patients, immediately after the injection, a venous sample was withdrawn from the opposite arm. These samples were collected in citrate solution and

99.7 per cent of the pools had macroscopic agglutinin titers, anti-A or anti-B, of less than 1:40. Also in 97 per cent the titer was less than 1:20.

5. In 355 small pools made up of plasma from 6 to 10 individuals, whereas the percentage with relatively low titers, 1:20 to 1:40, was somewhat higher than in pools of a larger number of plasmas, the percentage with titers of 1:40 or higher was not greater than in the larger pools. Therefore it is perfectly safe to prepare small pools of plasma from 6 to 10 donors. The probability of large plasma pools having a high titer is even less than that of small pools.

6. Pools of plasma were prepared entirely of type O plasma so as to secure the highest possible agglutinin titers, both anti-A and anti-B. These titers ranged up to 1:256. Seventy-five 500 cc. dried units of these plasma pools were reconstituted and administered intravenously to type A or B individuals. No reactions were caused, and there were no signs or symptoms of intravascular agglutination from the relatively high titered plasma.

7. Pooled plasma, as prepared in small pools at hospital blood banks or in larger pools at processing laboratories, the blood groups entering each pool by chance and without selection, can be administered with safety to all individuals, regardless of their blood types, and without fear of causing any harm because of isoagglutinin content or of causing any signs or symptoms of intravascular agglutination.

Clinical Notes, Suggestions and New Instruments

TREATMENT OF HUMAN PSITTACOSIS WITH PENICILLIN

HARRISON F. FLIPPIN, M.D., MICHAEL J. GAYDOSH, M.D., AND WILLIAM V. FITTIPOLDI, M.D., PHILADELPHIA

Previous reports have indicated that penicillin may be of value in the treatment of human psittacosis. Heilman and Herrell [1] demonstrated the protective effect of penicillin on mice experimentally infected with a strain of psittacosis virus of parakeet origin. According to Parker and Diefendorf [2] penicillin has a very definite effect on the course of the disease induced in chick embryos by the virus of psittacosis. Recently penicillin was employed successfully in a human case of ornithosis, which disease is caused by a psittacosis-like virus [3] Our purpose in this communication is to record a case of human psittacosis in which penicillin seemed to be of definite value.

REPORT OF CASE

History.—E. Q.; a white woman aged 52, was referred to the Philadelphia General Hospital Jan. 5, 1945 by her family physician, Dr. Philip Yuckman, because of a pneumonia that did not yield to sulfonamide therapy. Nine days before admission she complained of malaise, generalized body pains, frontal headache and a watery nasal discharge. By the fourth day of illness she had developed a hacking, nonproductive cough, sore throat, fever and frequent nosebleeds. For the next four days she received a total of 12 Gm. of sulfadiazine without improvement and on the ninth day of illness was admitted to the hospital.

Physical Examination.—The patient was acutely ill, mentally confused and restless, chiefly because of a rather severe unproductive paroxysmal cough. Her temperature was 104 F., pulse rate 100 and respiratory rate 30. The nose was oozing fresh blood and the pharynx was moderately inflamed. Over the left lower lung posteriorly there was some dulness to percussion and increased breath sounds. At both bases were heard many fine moist inspiratory and expiratory rales. The liver and spleen were not palpable.

Laboratory Studies.—The pertinent data pertaining to laboratory and x-ray [4] studies are shown in the accompanying illustrations. A report from Dr. K. F. Meyer [5] stated that a specimen of serum, obtained from the patient on the twenty-third day of illness, fixed complement in presence of psittacosis antigen 1:128 (4 plus). Because other diseases, especially lymphogranuloma venereum,[6] may produce high antibody titers with psittacosis antigen, a Frei test was performed and was negative. Stool and urine cultures as well as routine agglutination tests were all negative. The culture material contained para-aminobenzoic acid and penicillinase. The sputum culture showed a few pneumococci. Differential white blood counts were all normal.

Clinical Course.—The septic fever, paroxysmal nonproductive cough, nosebleeds, frontal headache and mental confusion persisted until the twenty-first day of the disease. Repeated chest x-ray examinations revealed a migratory type of pneumonia. Sulfamerazine was given with no effect, and on the nineteenth day of the illness the drug was stopped and penicillin 100,000 units intramuscularly daily was started. Within thirty-six hours of penicillin therapy there was definite clinical improvement. For the first time since admission the patient was clear mentally, the cough became less severe and the nosebleeds subsided. The administration of penicillin was followed also by a definite improvement in the lungs, as revealed by physical and x-ray examinations. Throughout the entire illness the physical chest signs were always less than the x-ray appearance. A relative bradycardia was present most of the time Recovery was uncomplicated, and the patient is now enjoying apparent good health.

Fig. 1.—Appearance of chest on thirteenth day of disease. Pneumonitis and some pleuritis involving the left lower lobe, with a peculiar irregular bronchopneumonic consolidation. In the right base there is only a small amount of pleural thickening, with early consolidation

Fig 2.—Appearance on twentieth day of disease The left lower lobe now shows much clearing and very little consolidation, but there is now a more recent area of consolidation in the left upper, the lower portion of the right upper and the right lower lobe There is a peculiar ground glass appearance in the consolidated areas

Fig 3.—Appearance on twenty seventh day of disease. There is now only a small amount of pleural thickening in the left base The pneumonic processes have entirely disappeared

Epidemiology.—In late September 1944, about three months before the onset of illness, the patient acquired a parrot Each day the bird was allowed out of the cage and would fly about the house. On Dec. 20, 1944, seven days before the illness began, the parrot bit the patient on her right middle finger. Aside from this episode there was no other history of contact with parrakeets, love birds, pigeons, doves or chickens.

SUMMARY AND CONCLUSIONS

The diagnosis of psittacosis in this patient is based on the history of a recent bite by a parrot, a migratory pneumonia which failed to respond to sulfonamides and a significant titer of complement fixing antibodies for psittacosis in the patient's serum. The Frei test was negative and there was no other history of contact with birds or animals which have been

shown to harbor psittacosis-like viruses. No attempt was made to isolate the virus, and we agree with Meiklejohn and his associates [7] that this is the only satisfactory positive evidence of specific infection. Nevertheless, we believe that this patient represents a case of psittacosis. Penicillin therapy was

"DIAPER RASH" DUE TO PERM-ASEPTIC

WILLIAM L. DOBES, M.D., ATLANTA, GA.

In recent months a new antiseptic solution has appeared on the market under the name of Perm-Aseptic-Ramplex. The product is sold as Perm-Aseptic for promotional purposes and as Ramplex for industrial purposes. The product is distributed by the Perm-Aseptic Process Company, New York City. The company advertises the new chemical as a fluid of highly concentrated power which combines the properties of germicide, bactericide and fungicide. According to the company's claims its purpose is to make textiles actively antiseptic as a protection to persons and as a prevention of destruction of textiles by bacteria, germs, mold and mildew.

Bacteriologic tests have been made by Foster D. Snell, Inc., and by the United States Testing Company, Inc. The zone of inhibition is claimed to be 3 to 6 mm. and to conform with the standard for laboratory tests as established by the Food and Drug Administration of the United States government.

Perm-Aseptic is becoming widely used among the diaper services. The diapers are passed through the Perm-Aseptic solution as the last rinse. The recommended dilution varies from 1:10,000 to 1:30,000.

Recently I have seen 5 cases of diaper rash which was caused by Perm-Aseptic. Three of these cases were thoroughly studied and followed.

The age of the infants varied from 2 months to 16 months. The rash appeared as an acute erythema accompanied by a mild edema of the areas involved. In 1 case vesiculation was present. Pruritus was moderate in all cases. The areas involved corresponded to the areas of contact with the diaper. The diapers in all the cases were supplied by a diaper service which in recent months added the Perm-Aseptic to the last rinse.

Three of the cases I had the opportunity to study. The mothers were told to boil the diapers and rinse them out in plain water before using. The diaper rash did not disappear but became less severe in 2 cases and remained the same in the third case. The Perm-Aseptic apparently is not completely removed by boiling and washing. It is claimed that even after several washings Perm-Aseptic is still present in the materials. The mothers were then told to use their own diapers for a few days. Each case rapidly cleared up within three to seven days. When wearing of the diapers from the diaper service was resumed the rash immediately reappeared. This was repeated three times in each case, thus confirming our suspicions that the diapers were the causative agent.

The United States Testing Company, Inc., reported on its patch testing as follows: "Twenty-five samples of cotton fabric previously treated with a 1-400 dilution of Perm-Aseptic Germicide, dried, were placed in contact with human tissue for forty-eight hours, removed for twenty-four hours and then replaced for twenty-four hours. No irritated areas developed on any individual." One of my own cases was patch tested with the diaper, which was passed through a 1:30,000 dilution as the last rinse. The patch test after twenty-four hours was positive.

I have communicated with Dr. Louis Schwartz of the U. S. Public Health Service, Bethesda 14, Md. According to the information received Perm-Aseptic is a primary skin irritant in strong concentration and a sensitizer in weak concentrations. So far cases of contact dermatitis from Perm-Aseptic have not been reported but are likely to occur as this new chemical becomes more widely used. It is evident that one exposure is not as likely to sensitize within three days as numerous exposures over a period of weeks. Each of my patients wore the diapers treated with Perm-Aseptic for at least two months before any symptoms of sensitivity appeared. The diaper service involved was most cooperative and because of the potential dangers the Perm-Aseptic was omitted from the washings. The cases involved have cleared up and no recurrence has been noted in several weeks, although the same diaper service is being used. The fact that the Perm-Aseptic was the only ingredient omitted by the laundry confirms the diagnosis of Perm-Aseptic being the offending agent in the cases of diaper rash described.

PNEUMONIC PLAGUE

REPORT OF A CASE WITH RECOVERY

EDGAR J. MUNTER, M.D., SAN FRANCISCO
Surgeon (R), United States Public Health Service

Recovery from pneumonic plague is so rare that for all practical purposes the disease is considered fatal. For this reason a case of proved plague pneumonia with recovery is thought to be worthy of recording.

Dr. J. H. was engaged in research investigations at the Plague Investigation Station of the U. S. Public Health Service, San Francisco, and had been so engaged for a period of eighteen months previous to his illness.

During the week before the onset of this illness he had been working with virulent cultures of Pasteurella pestis but had neither inoculated animals nor handled any that had been inoculated, and he had not made any significant changes in his customary bacteriologic technic. On May 31, 1944 he came to the laboratory as usual but returned to his home shortly after his arrival because of the onset of malaise and chilliness, which increased during the day and was accompanied by an occasional hacking cough. On awakening the following morning he found that his temperature was 104 F. and he coughed up some blood tinged sputum. He was promptly brought by automobile from his home and admitted to the U. S. Marine Hospital, San Francisco, at 10 a. m., June 1.

On admission he complained of malaise, slight pain in the chest, low down on the right side, and a frequent nonproductive cough. The patient was aware that he was confused and disoriented. His temperature was 104 F., the pulse rate 100, respiratory rate 26. His throat was slightly injected, but there were no enlarged cervical nodes noted. There was an area of impaired resonance at the base of the right lung posteriorly;

7. Meiklejohn, G.; Beck, M. D., and Eaton, M. D.: Atypical Pneumonia Caused by Psittacosis-like Viruses, J. Clin. Investigation 23: 167 (March) 1944.

the breath sounds were normal over this area, but there were very fine scattered rales. There was a faint systolic murmur heard at the apex of the heart, but otherwise there seemed to be no cardiac abnormality. The blood pressure was 110/70. The spleen was not palpable. The axillary and inguinal lymph nodes were not enlarged, and the skin of the head, neck, trunk and limbs was clear. The area of impaired resonance over the lung corresponded to a round patch of infiltration, demonstrated by a picture made by a portable x-ray machine (fig. 1).

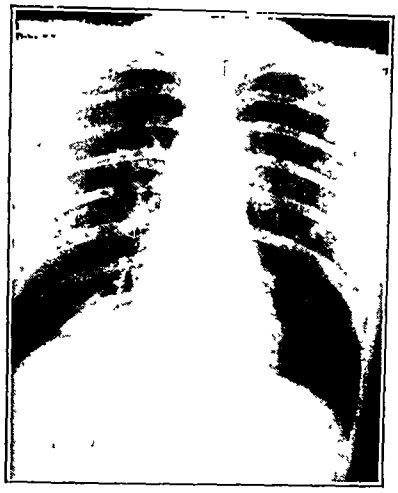

Fig. 1.—Area of consolidation in right lower lobe on entry, June 1.

Blood examination revealed 4,800,000 red blood cells, hemoglobin 13.6 Gm., 18,000 white blood cells, with polymorphonuclears 88 per cent and lymphocytes 12 per cent. The urine was normal. A specimen of approximately 4 cc. of sputum was obtained approximately twenty-four hours after onset through persistent coughing efforts. Examination of the sputum and the bacteriologic, chemical and other laboratory tests were done by the Plague Investigation Station, which is adjacent to the hospital.

The report of Dr. N. E. Wayson, officer in charge of the station, was as follows: "The sputum was very viscid and contained two rather discrete blood tinged portions. A microscopic smear of the blood tinged areas revealed large numbers of bacteria whose morphology and bipolar staining qualities were characteristic of Pasteurella pestis. In some portions of the smear these were the only organisms present and were scattered among leukocytes.

"Cultures of P. pestis were obtained directly from the sputum, checked through differential culture reactions and injected into mice and guinea pigs, which died with the pathologic changes characteristic of plague. Other mice and guinea pigs were inoculated with the sputum in amounts as small as 0.1 cc. by subcutaneous and intracutaneous injections. All died with the pathologic changes characteristic of plague, and pure cultures of P. pestis were obtained from the tissues of several of them. Mice were inoculated with small quantities of the sputum by intraperitoneal injection and their peritoneal contents were examined six to eight hours later for the presence of P. pestis and pneumococci. P. pestis but no pneumococci were found, and the animals were killed twelve and eighteen hours later. Cultures of pestis were obtained from the peritoneal fluid.

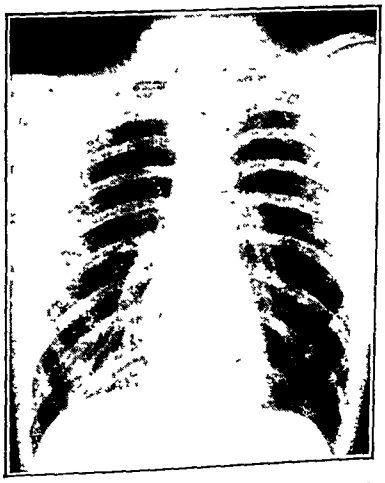

Fig. 2.—Almost complete absorption of lesion forty-one days after onset.

"Ten cc. of blood of the patient was inoculated into Kracke broth, to which para-aminobenzoic acid had been added, and incubated for a period of five days without the appearance of bacterial growth."

The course of the illness was severe and for the first four days the temperature remained between 102.2 and 106.8 F. rectally. Cough was hacking and frequent but not violent, and small amounts of bloody sputum were raised at irregular intervals. During the first six days the patient alternated between periods of delirium and periods of mental clearness, and at times he was so wildly irrational that it required repeated injections of morphine and scopolamine to restrain him. On two occasions, once after a chill and once after maniacal exertion, he developed severe circulatory collapse with cyanosis and dyspnea but improved each time after injections of morphine and of caffeine.

By the sixth day it was obvious that the temperature was falling by lysis, and that the patient's condition was definitely improving. His cough became much milder and the scanty sputum less blood streaked. After the sixth day plague organisms could not be recovered from the sputum by culture or animal inoculation, and after the eighth day he could raise no sputum at all.

The temperature became normal on the eighth day and remained so, but rales could be heard over the area of infection in the lower lobe of the right lung as late as the twenty-first day of the illness. At no time during the illness was there evidence of spread of infection to other lobes of the lung. He was allowed out of bed on the twenty-second day and returned to his home for a long convalescence on the twenty-sixth day. Electrocardiographic tracings taken during convalescence showed no evidence of myocardial damage. X-rays did not show complete clearing of the infiltration in the lung until six weeks had elapsed (fig. 2).

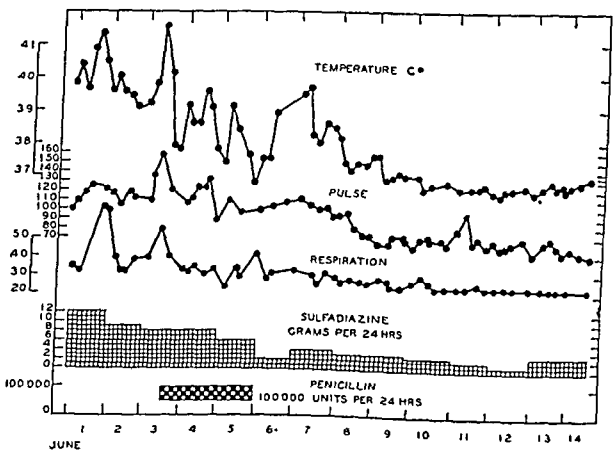

Fig. 3.—Temperature and medication.

Treatment was started immediately with large doses of sulfadiazine, 12 Gm. being given orally in the first twenty hours and 1 Gm. every four hours thereafter. After twenty-four hours the sulfadiazine level was only 4 mg. per hundred cubic centimeters. Two and five-tenths Gm. of sodium sulfadiazine was then given intravenously, and the oral dose was increased to 2 Gm. every six hours. However, the daily blood sulfadiazine level did not rise above 5 mg. per hundred cubic centimeters.

An antiplague rabbit serum was procured from the Hooper Foundation for Medical Research. Small doses of this serum were reported to protect mice against injections of P. pestis.[1] The patient was skin tested with the serum and was found highly sensitive to it and did not respond well to small desensitizing doses. It was believed that his condition was so precarious that a serum reaction might result fatally, and the serum was not used further.

On the fourth day of his illness intramuscular administration of penicillin was started, although it was understood that this drug has not been proved to be effective against infection with plague or other gram negative bacteria. Three hundred thousand units of penicillin was given and there was no evidence that the administration of this drug altered the course of the disease.

1. Meyer, K. F., director, Hooper Foundation for Medical Research: Personal communication to the author.

COMMENT

Primary pneumonic plague is usually fatal and therapeutic methods seem to be fruitless; it is generally attended with the development of secondary cases. However, recovery occasionally occurs [2] and secondary cases do not occur inevitably.

Antiplague serum has been used in the treatment of plague for many years and is reported to have prolonged life in cases of pneumonic plague for several days [3] There have been a number of reports of the favorable action of sulfonamide drugs in plague,[4] but in practically all instances the reference is to bubonic plague. Sulfathiazole has been repeatedly shown to be more efficacious than sulfapyridine in cases of bubonic plague, and animal experiments have seemed to indicate that sulfadiazine would be superior to either [5] In the reports of outbreaks of plague which show the apparent lowering of the bubonic plague mortality rate by the sulfonamides the cases of pneumonic plague have been fatal.

As far as I am aware, this case is the first to be reported in which primary pneumonic plague has been treated by the use of sulfadiazine and the patient has recovered However, the recovery cannot be attributed solely to a favorable action of this drug since other factors may have contributed to it

The patient had received five injections of plague vaccine over a period of six months, approximately one year previous to his illness. This vaccine had been made from virulent P pestis organisms which had been chemically killed Inoculations were made on Jan. 26, 1943, 0.5 cc.; February 2, 1.5 cc , April 3, 1.0 cc.; April 22, 1.0 cc.; June 11, 1.0 cc The total amount of vaccine injected contained approximately 122 billion organisms. Shortly after the last injection the administration of the patient's serum to mice afforded them protection against small doses of P. pestis. However, a rather unsatisfactory mouse protection test performed six months later on his serum showed no evidence of protection.

Further, the nature of the illness was recognized within twenty-four hours after its onset and he was afforded treatment with modern facilities very promptly. He was placed in an oxygen tent within an hour after his admission to the hospital, and his specific therapy was started approximately twenty-six hours after he first began to feel ill. He was given every nursing facility, and continued attention was directed toward the protection of his heart against undue damage by sparing him every possible exertion.

Cases of primary pneumonic plague do not invariably give rise to secondary cases even though there is a complete failure to quarantine or segregate contacts.[3] The absence of coughing, sneezing or otherwise infecting the atmosphere with droplets of the patient's sputum have been offered as the probable explanation of the failure of the secondary cases to develop in such instances. This patient had but little cough, but every effort was made to prevent the dissemination of droplets of his sputum in the surrounding atmosphere. It is believed that his treatment in an oxygen tent made an excellent screen between him and his nurses. The attending physician and the nurses were masked, hooded, gowned and gloved and spent the minimum amount of time necessary in the room occupied by the patient. All attendants other than his physician and the nurses assigned to his case were excluded from the three rooms devoted to his care. In order to enter the room occupied by the patient, it was necessary to go into a dressing room and from this through a second room in which all gowns and gloves used in the care of the patient were deposited in a phenol disinfectant previous to returning to the dressing room. As his physician, I carried on with my duties in other parts of the hospital in a somewhat limited manner, but the nurses remained under quarantine.

The manner in which this patient contracted plague is not known to him or to his laboratory associates. There is no evidence to suggest that the pneumonia was secondary to a septicemia following a local infection.

SUMMARY

A case of primary pneumonic plague was contracted accidentally during laboratory research The nature of the illness was recognized within twenty-six hours after its acute onset, and therapy with sulfadiazine was instituted at once. The patient had received a large amount of plague vaccine a year previous to the illness. He was placed in an oxygen tent promptly on admission to the hospital as a therapeutic and as a quarantine procedure, and other strict quarantine practices were carried out. Secondary cases did not occur.

Council on Foods and Nutrition

SPECIAL ARTICLE

This is the fifth of a series of articles discussing the significance of protein nutrition in health and disease. This material was prepared by the authors at the request of the Council and has been authorized for publication.

GEORGE K. ANDERSON, M.D., *Secretary.*

PROTEIN NUTRITION IN PEDIATRICS

S. Z. LEVINE, M.D.

NEW YORK

In addition to the many functions subserved by protein in adults, this foodstuff serves the special function in the child of providing basic building materials for the manufacture of tissues during growth. Protein also acts by virtue of its chemical and physiologic properties as a therapeutic agent in certain ailments peculiar to infancy and childhood; less commonly it may be biologically harmful when administered to children in its native state.

PROTEIN NEEDS FOR GROWTH

Protein needs for human growth are both qualitative and quantitative. Knowledge of these needs stems from studies on animals (notably the young white rat) and human observations including dietary surveys, measurements of nitrogen balance and creatinine excretion in urine and estimations of the rate and composition of growth at varying levels of protein intake and at different ages. Dietary prescription to meet these needs depends on such dietary factors as the biologic value of the proteins (amino acid mixture) ingested, their coefficients of digestibility, the degree of preparatory heating, the caloric, vitamin and mineral intake, sulfonamide medication [1] and such physiologic factors as pregnancy, puberty, the menarche, lactation, the state of nutrition and health, and age. Besides these known

conditioning factors, other issues of a more controversial nature preclude complete acceptance of currently established protein quotas for human growth: (*a*) the questionable validity of transposing to infants and children experimental data and conclusions derived from young animals and human adults;[2] (*b*) lack of acceptable clinical criteria for defining optimal as against average and maximal nutrition and protein requirements; (*c*) a paucity of quantitative information of the composition of essential amino acid mixtures conducive to optimal human growth.[2]

In the present state of knowledge an adequate protein intake for the infant and child may be defined as one which contains all the known essential (and perhaps nonessential) amino acids in sufficient amounts and in palatable and digestible form to cover maintenance needs and to provide in addition the surplus for protein deposition within the body compatible with normal growth.

Qualitative Considerations.—Proof is convincing that the young white rat grows in normal fashion when the sole source of dietary protein consists of a mixture of the following ten highly purified amino acids: arginine,[4] histidine, isoleucine, leucine, lysine, methionine, phenylalanine, threonine, tryptophan and valine.[5] Applicability of these results to other animals and to human beings is suggested by recent observations on the nitrogen balance of dogs,[6] infants [7] and adults [8] and on the manufacture of hemoglobin and serum proteins by animals and man [9] receiving natural proteins, amino acid mixtures as such or as casein hydrolysates. The nitrogen studies showed that positive nitrogen balances of similar magnitude resulted on equivalent intakes, irrespective of the source of dietary nitrogen. Pending long term observations of growth curves and physical fitness of infants and children receiving pure mixtures of essential amino acids, final proof is lacking that the rest of the protein molecule and its fourteen or more constituent amino acids are of no nutritional importance.[10] Furthermore, quantitative data on the relative importance of each of the essential amino acids are still sparse. The absolute amounts and percentage composition of amino acid mixtures conducive to optimal human growth are not yet known. Reliance for growth and maintenance of health remains with the natural protein foodstuffs; use of purified amino acid mixtures and casein hydrolysates is for the present reserved for the treatment of abnormal states in which the ingestion or assimilation of natural proteins is difficult or detrimental.[11]

TABLE 1.—*Percentage Amino Acid Composition of Proteins in Some Foods Commonly Used by Infants and Children* *

	Milk †				
	Lactalbumin	Casein	Egg	Meat	White Bread
Nitrogen	16.0	16.0	16.0	16.0	16.0
Arginine	3.5	4.1	7.0	7.2	3.5
Histidine	2.0	2.5	2.4	2.1	2.2

* Block, R. J., and Bolling, D.: The Amino Acid Composition of Proteins and Foods, Springfield, Ill., C. C Thomas, Publisher, 1945.

† The protein content of human milk averages 1.25 per cent (0.2 per cent nitrogen), the casein fraction comprising 0.0 per cent and the whey proteins (chiefly lactalbumin), 0.7o per cent. Corresponding values for cow's milk are 3.5 per cent protein (0.56 per cent nitrogen), 2.8 per cent casein, and 0.7 per cent whey proteins.

‡ Stare, F. J., and Hegsted, D. M.: The Nutritive Value of Wheat Germ, Corn Germ and Oat Proteins, Federation Proc. 3:120 (June) 1944.

Quantitative Considerations.—The quantity as well as the quality of dietary protein must be adequate to cover (*a*) maintenance needs [12]—the replacement or wear and tear quota and fecal loss—and (*b*) the growth quota. The wear and tear quota is a measure of metabolized protein. It varies with the caloric and protein intake and with the energy expenditure of the subject. It is estimated by analysis of the urinary nitrogen ($\times 6.25$). The fecal loss is a measure of the coefficient of digestibility of ingested protein and it is determined by similar analysis of the stools. In the absence of diarrhea and with the types and amounts of protein foods commonly used by infants and children, fecal loss of protein averages 10 per cent of the intake at all ages. The difference between the intake and the combined excretion in urine and feces or the magnitude of the nitrogen balance ($\times 6.25$) affords an estimate of the protein deposited in the body for physical growth and pre-

12 The specific dynamic action of protein is a by-product and not an integral part of the maintenance need for this foodstuff. On the usual milk diet of infants and in a ward diet of children this effect produces a rise of between 5 and 10 per cent above basal metabolic levels. Similarly, exercise does not raise the protein requirement, provided the total dietary calories are adequate.

sumably for other anabolic functions such as the manufacture of serum proteins and formation of enzymes, hormones and antibodies above antecedent levels.

Besides measurements of nitrogen balance, adequacy of the protein intake for growth is also judged by the rate and composition of gain in body weight. The latter may be estimated from the creatinine output in the urine and from the ratio of nitrogen retained to total accretion of body weight. A total gain of body weight conforming to the normal growth curve for height and age as estimated from standard weight tables, with the concurrent deposition of protein per unit of weight gain in amounts approximating the nitrogen content of the body as chemically determined (from 2.0 per cent in the newborn to 2.6 per cent in adults),[13] presumably characterizes an optimal state of quantitative and qualitative growth and nutrition.

Based on such evidence, the Food and Nutrition Board of the National Research Council has recently proposed daily allowances which may be accepted as an approximate guide of the protein requirements during growth. For physicians having a special interest in children, these allowances will serve a more useful purpose if they are amplified to include premature infants and broken down into shorter age intervals for the infantile period.

Provided the dietary protein is chiefly of animal origin and in digestible form and the regimen is adequate in all the other known nutrients, these allowances afford a good margin of safety for healthy infants and children. If a child does not thrive on this regimen the fault probably rests with him, his parents or the environment and not with the diet per se. On the other hand, it should be stressed that all dietary regimens are subject to modification. A diet should conform to the needs of the individual child and not the child to the diet.

TABLE 2.—*Recommended Daily Allowances for Protein, Expanded for the Growing Period*

Subject	Age	Protein in Grams * Total 1	Per kg 2	Per Lb. 3	% of Dietary Calories Average
Premature †	1 week to 1 month		6.0-4.4	2.7-2.0	17
Premature ‡	1 week to 1 month	4.3	5.0-4.4	2.3-2.0	15
Premature	1 to 3 months	per	4.4-3.3	2.0-1.5	13
Full term	2 days to 3 months	Kg	4.4-2.3	2.0-1.5	13
All infants	4 months to 1 year		4.0-2.0	1.8-1.4	13
Toddlers	1 through 3 years	40	(4.2-2.9)	(1.9-1.3)	(13)
Preschool	4 through 6 years	50	(3.7-2.5)	(1.5-1.1)	(13)
School	7 through 9 years	60	(2.6-2.1)	(1.2-1.0)	(12)
School	10 through 12 years	70	(2.2-1.8)	(1.0-0.8)	(11)
Youths, female	13 through 15 years	80	(1.8-1.5)	(0.8-0.7)	(11)
Youths, male	13 through 15 years	85	(2.0-1.7)	(0.9-0.8)	(11)
Youths, female	16 through 20 years	75	(1.6-1.4)	(0.7-0.6)	(13)
Youths, male	16 through 20 years	100	(2.1-1.7)	(1.0-0.8)	(11)

* Column 1 gives the allowances recommended by the Food and Nutrition Board, columns 2 and 3 the suggested modifications for infants. The figures in parentheses in these columns, beyond 1 year, represent the total allowances in the original recommendations (column 1) per unit of body weight on the basis of average weights for age groups derived from the tables of Baldwin and Wood.

† Premature infants weighing less than 2,000 Gm. (4 pounds 6 ounces).

‡ Premature infants weighing 2,000 Gm. and over.

The high level of protein intake advocated for young premature infants calls for an explanation. Many of these infants have difficulty in digesting and absorbing fat.[14] Their dietary calories are therefore preferentially derived from protein and carbohydrate. Human milk, when fed in the amounts needed to meet the high requirements for maintenance and growth (120 calories per kilogram, 55 per pound), furnishes, per kilogram of body weight, 180 cc. of fluid (2.7 ounces per pound), 2.2 Gm. of protein (1 Gm. per pound), 6.7 Gm. of fat (3 Gm. per pound) and 13 Gm. of carbohydrate (6 Gm. per pound). Although this level of dietary protein in the form of human milk is compatible with positive nitrogen balances of appreciable magnitude (between 0.2 and 0.25 Gm. per kilogram) the total fluid intake is excessive and the level of dietary fat frequently exceeds the fat tolerance of these subjects, especially of those weighing 1,500 Gm. (3 pounds 6 ounces) or less. For these and other reasons[15] heated cow's milk mixtures are preferred in the routine feeding of small and young premature infants.

TABLE 3.—*Formulas for Feeding Premature Infants per Kilogram of Body Weight and in Percentages of Dietary Calories*

Milk Type	Milk Amount, Cc.	Milk Sugar, Gm.	Milk Water, Cc.	Protein Gm.	Protein Per Cent	Fat Gm.	Fat Per Cent	Carbohydrate Gm.	Carbohydrate Per Cent	Calories
Human	180	..	0	2.2	7	6.7	50	12.9	43	120
Cow's										
Whole	100	13	50	3.5	13	3.5	27	17.8	60	120
Lactic acid	140	6	..	4.8	16	5.5	41	12.9	43	120
Evaporated	70	6	80	4.8	16	5.5	41	12.9	43	120
Powdered half skimmed (Alacta)	18	11	150	6.0	20	2.2	16	19.4	64	120

In isocaloric amounts (120 calories per kilogram) cow's milk mixtures may be prepared to provide less total fluid and fat, higher protein, and equivalent or higher carbohydrate. Examples of such mixtures are given in table 3. Comparative studies of such mixtures of heated cow's milk and of unmodified human milk for the past ten years in the premature unit of the New York Hospital[16] favor the former feedings. The daily gain in total body weight is more constant and at higher levels (25 to 30 Gm. as against perhaps 15 to 20 Gm.), the nitrogen balances are of higher magnitude (0.3 Gm. or more per kilogram as against 0.25 Gm. or less) and the coefficient of digestibility of the more liberal protein intakes is not reduced (85 to 90 per cent at all levels of dietary protein). It may further be pointed out that intakes of human and heated cow's milk of equivalent but lower protein content (2 to 3 Gm. per kilogram) yield absolute and percentile retentions of nitrogen of similar magnitude (0.2 + Gm. per kilogram and above 50 per cent of the intake[17]). This parity of utilization above maintenance levels of the proteins of human and cow's milk for growth in premature infants, contrary to the findings in animals,[18] is in accord with expectation on the basis of the qualitative similarity of amino acid composition of the milk proteins, casein and lactalbumin, noted in table 1. For

heavier and older premature infants, better able to tolerate fat and high fluid intakes, human milk is as satisfactory as cow's milk mixtures of higher protein content.

As the absolute rate of growth decelerates in later infancy, the protein intake may be correspondingly reduced to the recommended daily levels of 3 to 4 Gm. per kilogram of body weight. Concomitant with this decline in total increment of daily weight gain, the absolute and percentile retentions of dietary protein at equivalent and adequate intakes has been found to decline from average levels of 0.3 Gm. of nitrogen per kilogram or above 50 per cent of the intake in premature infants and of 0.2 Gm. or less than 40 per cent in full term infants under 3 months of age to average levels of 0.15 Gm. or 15 per cent for infants 5 months of age and older.[19] Analysis of available data for infants under 1 year establishes that the recommended daily allowances of protein as modified in table 2 are compatible with a normal rate of total weight gain and a ratio of nitrogen retained to total increment of gain which approximates the rising nitrogen content of the body (from 2.0 per cent at birth to more than 2.5 per cent during the growing period [20]).

Protein intakes below 2.2 Gm. per kilogram (1 Gm. per pound) in infancy may lead to negative nitrogen balances; levels above those recommended are wasteful since there are no body depots for reserve protein, absorbed amino acids in excess of the needs for growth and maintenance entering interchangeably with fat and carbohydrate into the energy exchange; excess of dietary protein may tax the kidneys by increased excretion of nitrogenous end products, and some of the incoming amino acids may be incompletely metabolized by the young infant in the absence of added vitamins.[21]

With further deceleration in the growth curve with increasing age beyond infancy, lower levels of dietary protein per unit of body weight are required for nitrogen retention and protein deposition. The daily allowances recommended by the National Research Council are generally acceptable. Based on average weights for each group, these allowances progressively fall from a maximal level of 4 Gm. per kilogram at 1 year of age to 1.4 Gm. per kilogram for girls of 20 years. The percentage of dietary calories (at the recommended levels) derived from protein remains constant between 11 and 13 per cent for all ages. The bulk of available evidence indicates that the recommendations are compatible with normal qualitative and quantitative nutrition as judged by dietary surveys, nitrogen balance studies, urinary excretion of creatinine, growth curves and clinical appraisement.[22] Some observers report improvement in measurements of children of preschool and school age on higher protein intakes of 4 Gm. as against 3 Gm. per kilogram.[23] Whether such acceleration is desirable raises the perennial question of maximal versus optimal nutrition, a problem which awaits further study and clarification. It seems valid to state that in the presence of undernutrition from any cause the higher allowances are preferable.[24]

Dietary Prescription.—Human or cow's milk ordinarily comprises the sole protein-containing food in early infancy. The protein content of human milk averages 1.25 per cent (0.75 per cent whey proteins, 0.50 per cent casein), that of cow's milk, 3.5 per cent (0.7 per cent whey proteins, 2.8 per cent casein). Since both casein and the whey proteins of milk contain abundant and comparable amounts (per gram of protein) of all the amino acids (except leucine) essential for growth in young animals and presumably in infants (table 1), the protein needs for growth are automatically met by providing sufficient milk. The concept of a higher biologic value of human over cow's milk, erroneously postulated on the basis of a deficiency of cystine in the casein fraction, has been discarded since it has been shown [25] that methionine and not cystine is the sulfur-containing amino acid required for growth and that cow's milk contains the latter amino acid in concentrations as high as or higher than human milk. From the standpoint of protein alone, it seems fair to conclude on the basis of current information that in equivalent content of protein above maintenance levels the two milks are equally nutritious.

A daily allowance (from the first few days after birth) of 175 to 200 cc. of human milk per kilogram of body weight (2½ to 3 ounces per pound) or of 100 to 130 cc. of heated cow's milk (1½ to 2 ounces per pound) covers the protein needs of young full term infants. The daily allowance of cow's milk for young premature infants, as previously indicated, is better set at somewhat higher levels (130 to 140 cc. per kilogram). For older infants in both groups the lower levels are adequate.

When the infant is old enough to take additional foods, other proteins of animal origin (eggs, meat, cheese, fish) and some vegetable proteins (cereals, bread, potato, legumes) progressively replace milk as the sole source of protein. It is a good rule to limit the daily intake of milk in the infantile period to a maximum of 1 liter (quart) and to introduce solid foods in the diet at around 4 months. In children above infancy, from two thirds to three fourths of the total protein intake is preferably derived from animal sources, approximately 50 per cent of total dietary protein being supplied by milk (750 cc. or 1½ pints), 25 per cent by meat and eggs, 15 per cent by bread, cereals and potato, and the remaining 10 per cent by fruits, vegetables and other foods.[26] Dietary surveys reveal that the amounts and distribution of protein in the daily diets of growing children are below the

recommended levels in many parts of the country.[27] The quantities and sources of proteins in the common foodstuffs are reviewed in another paper of this series.[28]

PROTEINS IN DISEASE

The role of proteins and their constituent amino acids for growth in health is likewise important in such abnormal states as malnutrition, obesity treated by reduction diets, epilepsy treated by ketogenic diets, diabetes mellitus, recovery from acute illness and in the course of chronic disease. Fever, starvation and malnutrition further deplete the already meager stores of body protein, which are of lower magnitude to begin with in children than in adults and in those whose rate of metabolism is higher. The heightened needs in these conditions require attention in planning dietary regimens.

Besides this generally increased demand for protein in illness, this foodstuff by virtue of its unique properties serves a specific role as a therapeutic agent in certain states. The roles of protein and amino acid therapy in pregnancy, lactation and disease are reviewed in other papers of this series.[29] This section presents a brief outline of the use of protein in some disorders common to infants and children.

Disorders of the Alimentary Tract.—In health the coefficient of digestibility of protein is high, only 10 per cent or so of the intake being lost in feces. This high tolerance for protein is least impaired of all the organic foodstuffs in most digestive disturbances of infants and children. This fact, doubtless ascribable to the high levels even in early infancy of gastric rennin and pepsin, pancreatic trypsin and chymotrypsin and intestinal peptidases, explains the usage of properly heated milk mixtures, relatively high in protein and low in fat and carbohydrate, as the common method of resumption of enteral feeding in the recovery period of epidemic diarrhea of the newborn and infantile diarrhea of enteral and parenteral origin. Such mixtures include protein milk, skimmed lactic acid milk and skimmed milk with or without added casein. For analogous reasons, diets of high protein content form the basis of regimens in such specific disturbances of the alimentary tract as pancreatic fibrosis, the celiac syndrome (chronic intestinal indigestion) and ulcerative colitis, in the absence of an allergic basis for the two latter conditions.

Since ample evidence is at hand to show that the minimal amounts of unaltered protein normally absorbed into the blood stream are increased in digestive disturbances in early life,[30] predigested proteins in the form of enzymatic casein hydrolysates are gradually replacing native proteins in treatment during the acute stage of many of these conditions.[31] This form of therapy has the advantage of minimizing the hazard of subsequent hypersensitiveness.

Conditions Associated with Edema.—The importance and explanation of action of the blood serum proteins in regulating oncotic pressure relationships and fluid balance in the body are well known. They rise normally from average levels of 5.5 Gm. per hundred cubic centimeters at birth (albumin 3.8 per cent, globulin 1.7 per cent) to 7.0 Gm. per hundred cubic centimeters (albumin 5.0 per cent, globulin 2.0 per cent) at 2 years. The specific property of the serum proteins, particularly the albumin fraction, of combating edema forms the basis for the abundant administration of this foodstuff in such conditions of infancy and childhood as nutritional edema, infectious colitis, lipoid nephrosis, extensive burns, other states inducing shock, and juvenile cirrhosis of the liver. The hypoproteinemia common to all these conditions is explained in the 6 instances respectively by inadequate intake, excess fecal loss, excessive urinary excretion, skin seepage, plasmapheresis or hemorrhage, and defective production within the body. Natural proteins by mouth, enzymatic casein hydrolysates enterally and parenterally, whole blood, plasma and serum transfusions have been used with varying effect. The reader is referred to the other papers of this series and to other articles[32] which review the relative efficacy and the amounts of these substances recommended for therapy.

Allergic States.—Food allergies are more common in infants and young children than in later life. This predilection is probably explained by the greater permeability of the intestinal tract of these subjects to unaltered protein.[33] The most commonly implicated protein foods are milk, egg, meat, fish and wheat. In order of increasing age, clinical sensitivity to protein is manifested by infantile eczema, angioneurotic edema, mucous colitis and bronchial asthma. Detection of the responsible protein or proteins is made preferably by therapeutic test (ingestion) or by skin tests. If possible, avoidance of the specific foodstuff with the substitution of other protein foods is the therapeutic method of choice. If this cannot be done, immunization (desensitization) may be attempted. Because of the biologic nonspecificity of amino acids, such mixtures, as they become more readily available, will undoubtedly serve an increasingly important therapeutic role in these conditions.[34]

An attempt has been made in this brief review to evaluate the specific role of protein in pediatrics. It should be emphasized, in closing, that many conditioning factors, both dietary and physiologic, influence the requirements for this foodstuff, and that they must be given consideration in the dietary prescription of protein for infants and children in health and in disease.

SATURDAY, MAY 26, 1945

PERMISSION FOR MEETING OF HOUSE OF DELEGATES DENIED

On April 23, 1945 application for a permit to hold an annual meeting of the House of Delegates of the American Medical Association in Chicago July 23 to 25, 1945 was forwarded to the War Committee on Conventions of the Office of Defense Transportation in Washington. On May 17 the following letter was received from the secretary of that Committee:

WAR COMMITTEE ON CONVENTIONS
Washington 25, D. C.
May 15, 1945.

American Medical Association
Dr. Olin West, Secretary
535 N. Dearborn Street
Chicago 10, Illinois

Dear Dr. West:

Your application for a permit to hold an annual meeting of House Delegates at Chicago, Illinois, July 23-25, 1945, at the Palmer House, has been reviewed by the Committee.

It is the consensus of the Committee that this meeting should be deferred. Therefore, permit is denied.

This action does not preclude your holding a meeting attended by not more than 50 persons from out of town, plus local attendance without numerical limitation.

Very truly yours,
(Signed) Frank Perrin
Frank Perrin, Secretary.

Having been informed that it would not be possible to secure permission for a meeting of the House of Delegates during the month of June, it was requested in the application for a permit that a meeting might be held on July 23 to 25 with the view that those dates would antedate the movement of large numbers of troops from the European areas to the United States. It will be noted in the letter from the secretary of the War Committee on Conventions that it is the feeling of the members of that committee that the meeting of the House of Delegates should be deferred.

Application for a permit to hold a meeting at a later time will be submitted to the War Committee on Conventions.

ARTIFICIAL KIDNEY

Abel, Rowntree and Turner[1] devised in 1912 a method by which the blood of a living animal may be submitted to dialysis outside the body and again returned to the circulation without exposure to air, infection by micro-organisms or any alteration which would be prejudicial to life. The apparatus constituted a sort of artificial kidney, and the process was called by the authors "vivi-diffusion." An extract of hirudin prepared from the heads of leeches was used to keep the blood from coagulating. Excretion of salicylic acid by the apparatus showed that 19.1 per cent of the drug injected into the femoral vein of a dog was excreted in seven hours. The principle of the method consists in connecting an artery of the animal by a cannula to an apparatus made of celloidin or other dialyzing membrane in the form of tubes immersed in a saline solution or serum, and providing for the return of the blood to the animal's body by another cannula attached to a vein. These authors were interested primarily in obtaining, by the process of dialysis of blood, a large quantity of the nonprotein amino bodies for purposes of study. They did, however, indicate therapeutic possibilities of the process.

Thalhimer[2] in 1938 reported experiments in which "exchange transfusion" was practiced. Blood from an animal rendered azotemic by a bilateral nephrectomy performed the day before the transfusion was transferred into a normal dog, and the reverse. A small amount of heparin was injected intravenously into each animal. The exchange of blood was carried out twenty to forty times. The azotemia of the nephrectomized animal was much reduced; correspondingly, azotemia was produced in the donor animal. The donor animal's condition was normal the morning after, and the blood urea had returned to a normal level. The kidneys of the donor animals, killed from one to three weeks later, were found to be normal both on gross and on microscopic examination. Thalhimer repeated the experiments of Abel and his associates, using cellophane tubes as a dialyzing membrane and heparin as the anticoagulant. In from three to five hours 200 to 700 mg. of urea nitrogen passed from the blood through the cellophane membrane into the surrounding isotonic solution of sodium chloride. Thalhimer suggested that the method could be used on human beings in certain conditions in which, as a result of accident, operation or disease, previously competent kidneys become incompetent, leading to azotemia and death.

Thalhimer, Solandt and Best[3] repeated exchange transfusion experiments on dogs, utilizing a specially designed pump which had a capacity of at least 30 liters

an hour in each direction. Sufficient highly purified heparin was injected intravenously before and during the transfusion to prevent thrombus formation. The heparin did not appear to have any toxic action. The urea of the azotemic animal was rapidly excreted in the urine of the normal dog. The donor dog may recover completely after the termination of the experiment.

Kolff and his associates [4] working at Kampen (the Netherlands) developed a dializer consisting of a cellophane tube 25 mm. wide and 30 meters long. This tube is only partly filled with blood, giving a much larger surface area. The tube is wound spirally around the cylinder, the motion of which moves the blood from left to right. The rinsing bath contains 70 to 100 liters of tap water warmed up to 37 to 39 C. To this solution is added 0.7 per cent of sodium chloride, 1.5 per cent of glucose and 400 mg. of heparin. The patient receives a similar amount of heparin at the beginning and 100 mg. every half hour. The apparatus, according to the calculations of the authors, represents a dialyzing area of 23,000 sq. cm., the total area of the human glomeruli being 20,000 sq. cm. With this apparatus the Netherlands workers were able to reduce the blood urea and keep it at the same level for twenty-six days in a woman aged 29 who was in a state of impending uremia, with blood urea of 164 mm., blood pressure of 220/140 and uremic breath. The clinical symptoms of uremia in the course of the treatment were considerably improved after each dialysis. Unfortunately a number of intervening complications, such as pericarditis, parotitis and purulent bilateral otitis media, compromised the beneficial effect of blood washing and led to death. In their larger dialyses in this patient, 24, 40 and 35 Gm. of urea were dialyzed out respectively. The largest quantity of urea excreted by the patient in twenty-four hours in her urine amounted to 12 Gm. In addition to urea, uric acid, creatinine and residual nitrogen are being removed from the blood by dialysis. If it is desired to compensate the loss of sodium chloride or glucose from the blood, these substances can be added to the rinsing bath, since the molecules pass both in and out through the dialyzing membrane. If necessary, other substances, such as calcium, magnesium or potassium, may be added to the bath water. The authors treated 2 more patients with the artificial kidney, but both were hopeless from a clinical standpoint. However, 100 Gm. of urea was removed from 1 patient in six hours, the blood urea of the patient showing a decline from 460 to 290 mg.

From the experiences of these authors the artificial kidney of the future apparently would not find its greatest usefulness in patients with chronic nephritis and uremia; these lesions are irreversible. As originally suggested by Thalhimer, dialysis of the blood may find its application in instances in which an individual with previously competent kidneys suddenly develops loss of renal function, as after a severe burn, in a prostatic patient who develops anuria after relief of intravesicular pressure, and in anuria after operative procedures. Conceivably if the renal secretion is temporarily taken over by the artificial kidney the patient's kidneys may return to their previous competence.

NASAL STAPHYLOCOCCI AND WOUND INFECTION

Staphylococcus aureus can be isolated from the nasal cavity and skin of healthy human subjects with amazing frequency. Miles and his associates [1] have demonstrated that the nasal carrier rate for Staphylococcus aureus among people of the working class of Birmingham who come to the hospital for the first time fluctuated between 19 and 65 per cent during the period October 1942 to July 1943. The mean rate, 47.4 per cent, agrees with carrier rates that have in the past been determined mainly in hospital patients and personnel. The people studied in Birmingham consisted of three groups: (1) outpatients attending the hospital for the first time with newly inflicted wounds, (2) male inpatients in a ward with established wound sepsis and (3) the nursing staff of the same ward. The 479 outpatients had a gross nasal carrier rate of 47.4 per cent and a wrist carrier rate of 18.4 per cent. The nasal carrier rate of the 536 inpatients, calculated from their admission swabs, was 49.4 per cent. The nasal carrier rate among the nurses was significantly higher than for the newly admitted patients. The authors also demonstrated that a patient found to be a carrier on a given date had a 70 to 75 per cent probability of carrying the organism at the time of wounding, if that occurred within fourteen days of the date of swabbing. There is a similar probability that he would be capable of contaminating his wound with nasal staphylococci for at least fourteen days after that date. The carriage or noncarriage of staphylococci therefore appears to be a more or less persistent phenomenon. There appears to be a relationship between the nose and skin carriage of staphylococci; although only 24.7 per cent of nasal carriers were also skin carriers, the percentage of skin carriers among those not carrying in the nose was only 12.7. In a limited study of 16 cases the authors found by phage typing that in 15 the strains from nose and skin were identical, and in only 1 were they dissimilar. Gillespie and his associates [2] demonstrated a similar degree of association and showed that in a number of their cases the nasal and the skin strains were of the same serologic type. The greater incidence of nasal carriage and the greater profusion of staphylococci found in the nose

1. Miles, A. A.; Williams, R. E. O., and Clayton-Cooper, B.: The Carriage of Staphylococcus (Pyogenes) Aureus in Man and Its Relation to Wound Infection, J. Path. & Bact. **46**: 513 (Oct.) 1944.

2. Gillespie, E. H.; Devenish, E. A., and Cowan, S. T.: Pathogenic Staphylococci: Their Incidence in the Nose and on the Skin, Lancet **2**: 870 (Oct. 21) 1944.

of carriers as compared with that on the skin of the wrist suggests that the nose is the primary source of the cocci found on the hand.

The course of wounds on the hands of patients whose nasal and skin carrier state was determined on the day of wounding suggested to the authors a relationship between carriage on the wrist of one hand and early staphylococcus contamination of a wound on the other. This supposition finds some support in the fact that in a limited study of 18 patients similar phage types in the wound and on the skin were found in 13 patients, while in 5 they were dissimilar.

Self infection, therefore, while probably not as important or prevalent as cross infection of wounds, appears from this study to be a definite factor requiring special preventive measures in medical and surgical wards.

MITOTIC STIMULATION OF WOUND HEALING

In 1943 Claude and Potter [1] of the Rockefeller Institute isolated chromatin threads from the resting nuclei by purely mechanical means. The frozen spleens of leukemic rats were thawed and ground gently for three minutes with an equal weight of beach sand. With the temperature below 5 C. the resulting mixture was suspended in six times its weight of isotonic solution of sodium chloride, the suspension being maintained at p_H 7.4 throughout the experiment. The suspension was then centrifuged for one minute in an ordinary laboratory centrifuge (1,500 × gravity) and the resulting sediment discarded. The supernatant fluid was then submitted to ten minutes' centrifugation at the same speed. This "long run", centrifugation brought down an abundant sediment of threadlike material. The threadlike precipitate was resuspended in slightly more than an equal volume of saline solution and the "long run" centrifuging repeated two times. The entire process was completed within one hour. Rapid separation and low temperature are essential to prevent autolysis.

Microscopically the chromatin mass thus obtained was composed of filaments ranging from 0.5 to 1 micron in diameter. These were apparently identical in size and shape with the preformed chromatin strands of resting nuclei. Chemical analyses and tinctorial reactions confirmed this identity.

Aside from its general biologic interest the new chromatin preparation may have clinical value owing to its stimulating effect on the rate of mitosis when administered to experimental animals. Marshak and Walker [2] of the University of California found that, administered intravenously, Claude's chromatin extract from rat tissues hastens the rate of mitosis in the regenerating rat liver. Applied locally the chromatin preparation greatly accelerates the rate of healing of superficial skin wounds.

For a quantitative study of the rate of wound healing the California investigators [3] devised a technic for producing skin wounds of uniform depth and size. A stainless steel tube was ground at one end to make a circular cutting edge 6.6 mm. in diameter. With this trephine a depression was made in the skin on the back of the neck of an anesthetized rat. Along this line the skin was cut with a pair of iridectomy scissors through the dense connective tissue of the dermis but not through the loose connective tissue of the hypodermis. The skin thus circumscribed was lifted off without dissection. There was usually no bleeding. What little did occur was easily controlled with a small swab so that the wound did not contain blood clots. A thick solution of methacrylate polymer dissolved in toluene was then dropped on the wound, and the adjacent skin painted with the same solution to make a coat extending 3 to 5 mm. beyond the wound. On drying, contraction did not occur, as was the case with some other plastics. The plastic dressing did not adhere to the wound but did cling to the surrounding normal skin, where it acted as a splint, preventing contraction.

To study the effect of chromatin on the rate of wound healing 2 or 3 small drops of 0.12 per cent chromatin extract in saline solution was placed on the wound so as to fill the skin defect. The plastic dressing was applied over the filled wound and the adjacent normal skin. Control animals were treated in the same way except that sterile saline solution was substituted for dilute chromatin. In a typical control experiment only 3 of 15 rats showed any signs of wound healing by the fifth day. This appeared as a band of granulation tissue less than 1 mm. in width about the periphery of the wound. In contrast, 13 of the 16 chromatin treated wounds of the same series showed granulations covering from one fourth to two thirds of the entire wound area, an average of twenty-five times the average area covered in the untreated controls.

The granulation tissue in the chromatin stimulated wounds was bright red, as compared with the light pink of the untreated controls. Microscopic sections showed greater vascularization. After epithelization was complete, the elevation of the chromatin treated wound above the surrounding skin was no greater than that of the untreated controls.

Subsequently Howes [4] showed that chromatin extract administered intravenously to rabbits maximizes the rate of healing of superficial wounds of the ear. The chromatin preparation also causes greatly increased

growth rate of fibroblasts in tissue cultures. Detailed studies of its immunochemical specificity and of its stimulating effects on the rate of mitosis in regenerating internal organs are now in progress.

Current Comment

INDUSTRY NEEDS MEDICINE

Plant 1 of the Eastern Aircraft Division of General Motors Corporation is located at Tarrytown, N. Y. Recently the Westchester County Medical Society was invited to hold its regular monthly meeting at this plant. Two hundred and fifty members attended a most interesting session. Events included a tour of the plant, inspection of the facilities and methods employed in the medical department, and dinner in the plant cafeteria. During the formal program later a film on industrial hygiene was shown. The plant medical director described relations with the medical profession, and the chief medical consultant to the corporation described medicine's contribution to the war effort in terms of maintaining industrial manpower in good health and on the job. Here intelligent industrial management demonstrated its need for medical service. This medical requirement can and should be part of the fabric of community medical service and planning. The physicians of Westchester County realize better than before that conflict need not exist between the proper objectives of industrial medicine and the best interests of their patients. The Council on Industrial Health feels that improved standards of industrial medicine depend largely on local medical organization, education and leadership expressed through committees on industrial health in state and county medical societies. The results in Westchester County indicate that opportunity awaits mutual understanding and instruction between industry and the allied professions of medicine, dentistry, engineering and nursing.

THE ROCKEFELLER FOUNDATION IN 1944

During 1944 the Rockefeller Foundation appropriated about $4,500,000 for public health and the medical sciences. The largest part of the budget was devoted to the International Health Division. In his presidential report, Fosdick [1] suggests that the most significant contribution of this division has been in the field of public health education. During 1944, for example, substantial sums were appropriated for fellowships and travel grants and for the support of schools of hygiene and public health nursing. A dramatic aspect of the activities of the International Health Division was the work of the typhus team under Dr. Fred L. Soper. The foundation has continued its activities also in yellow fever and in psychiatry. The accelerated program of medical education and the consequent comparative inadequacy of training of many young medical graduates has been studied by the foundation. In December 1943 the foundation made an appropriation to extend the postwar training of medical graduates returning from the armed services, and an additional sum was appropriated in 1944. The purpose of the foundation's new fellowship program is to make it possible for twenty-one leading medical schools to offer a limited number of residencies to the best of the younger medical graduates when their war work is done. The residencies thus offered are to pay stipends adequate for the individual case. One of the grants of the foundation was to the University of Michigan School of Public Health for the teaching of medical economics under Nathan Sinai, Ph.D., well known as a fluent and persistent advocate of federally controlled socialized medicine. He recently appeared in California as a guest of the governor's office, in a legislative hearing, to support compulsory sickness insurance in that state. The Rockefeller Foundation, with funds that are small compared with present day government spending, has until recently exerted a profound and on the whole beneficial influence in medical and public health fields.

1. The Rockefeller Foundation—A Review for 1944, by Raymond B. Fosdick, New York, 1945.

WORLD AREAS OF RAPID POPULATION GROWTH

Medical practice and public health procedure will be influenced inevitably by the enormous changes in total and relative populations of various sections of the world during the next fifty years. The medical profession should have a basic conception of what present trends may mean to medical care and to the world's health. A study of areas of rapidly growing populations containing chapters on the demography of Japan, India, eastern and southern Europe, the Near East and Egypt has been published recently by the Milbank Foundation Memorial Fund.[1] India, for example, increased its population by over 50,000,000 between 1931 and 1941; the population now almost certainly exceeds 400,000,000. If this growth should continue at the rate of the relatively favorable years from 1931 to 1941 the population would double itself in fifty-seven years, i. e. reach a total of over 800,000,000. In the primarily agricultural economies both the birth and the death rates are exceedingly high in comparison with the more urbanized and economically developed countries of western Europe and the United States. Part of the dilemma facing the world is indicated by the certainty that improved sanitary, dietary and personal hygienic measures, if applied to such countries as India, would reduce the death rate with little, if any, early effect on the birth rate. The inevitable result would be an enormous increase in population which would be faced by extremely low standards of living and a greatly increased probability of starvation and epidemic disease. As pointed out by Notestein in the final chapter of this book, there is no easy solution. Certain procedures can reduce the dangers inherent in the continued rapid and enormous increase in population of some areas. The provision of medical care and public health administration to these areas of rapid growth will doubtless be a colossal problem.

MEDICINE AND THE WAR

ARMY

WOMEN DOCTORS ASSIGNED TO IMPORTANT TASKS

Eleven commissioned women doctors are serving with the U. S. Army Medical Service in the European theater of operations in capacities that range from general hospital ward surgeon to assistant medical military attaché in the American Embassy, London.

Three of these women doctors arrived in England late in 1941 at the request of the British Ministry of Health because of the critical shortage of surgeons and physicians after Dunkirk. Major Marion C. Loizeaux, Wellesley, Mass., was the first woman doctor to be commissioned in the European theater. Formerly an assistant physician at Wellesley College, she is serving on the staff of Major Gen. Paul R. Hawley, theater surgeon, as a special consultant in all matters pertaining to the medical care of the Wacs.

The two other doctors who were volunteers and are in the European theater are Capt. Eleanor Peck, Poughkeepsie, N. Y., who is assigned to the Shaef Dispensary, and Capt. Josephine Stephens of Monongahela, Pa., who is assigned to a general dispensary in Paris. A fourth, Capt. Mila Pierce, Chicago, who was a general hospital ward officer, was returned to the United States recently after she had fallen and broken her hip.

These four physicians—among twelve women doctors selected from five thousand applicants by the British Ministry of Health—were in England to greet the American Army when it arrived overseas. The four were first accepted by the U. S. Army medical service as contract surgeons and were later commissioned. Major Loizeaux was made a captain in September 1943, and the others were commissioned shortly thereafter.

Another of the twelve women doctors who served with the British as a volunteer is Major Sally Bowditch, Boston. She is assistant medical attaché to the American Embassy in London—the first woman attaché in the embassy's history. She returned to the United States at the request of Johns Hopkins University and was commissioned there in November 1943.

Included on the medical staff of a newly arrived general hospital are four women doctors: Capt. Jessie D. Read, Westfield, N. J.; Capt. Clara Raven, Youngstown, Ohio; Russian born and educated Capt. Bronislava Z. Reznick, Chicago, and 1st Lieut. Elvira C. Seno, Burlington, Wis.

Capt. Martha Howe, New York, is a recent arrival in England from the Mediterranean theater and is now a surgical ward officer in a general hospital. First Lieutenant Jean Dunham, North West Washington, D. C., anesthetist with a general hospital in England, was recently promoted to the rank of captain. Capt. Katherine E. Jackson, Fort Wayne, Ind., is an anesthetist with a general hospital. She spent five weeks doing forward area work with field and evacuation hospitals before her own unit began actual operation. A member of the twelve original women doctors who went to England as volunteers, Major Barbara Stimson, Royal Army Medical Corps, is serving with a British hospital in Italy.

There are approximately seventy-five women doctors in the U. S. Army Medical Department in all theaters.

CHEMICAL WARFARE SERVICE DESIGNS GAS MASKS

The War Department recently announced that the Chemical Warfare Service recently designed three gas mask sizes which will fit all soldiers in the Army. Ten different head types were established, five normal and five unusual. The selection on types was made by correlating measurements representing breadth, depth and length of the face. The normal type comprises an average head and two large and two smaller sizes. The unusual types are those in which two of the principal measurements correspond with normal heads but whose third major measurement does not. It was found that 65 per cent of the soldiers measured normal medium, 19 per cent medium small and 11 per cent medium large. Four per cent of the heads were small, 3 per cent large. In the unusual size, 7 per cent had "short fat faces," the largest single category in that group. The study was carried on at Camp Sibert, Alabama, where 3,075 men representing every state in the Union, Alaska and the Philippines were tested for facial and cranium measurements. The birthplace of the soldier, and the nationality of his father were taken. Facial characteristics such as fleshiness of the face, prominence of the cheek bones, pointedness of the face, prominence of the forehead, structure and shape of the nose, size of lips and whether ear lobes were attached to the face were also noted.

HOSPITAL TRAIN UNIT RECEIVES MERITORIOUS SERVICE PLAQUE

While evacuating wounded from the Seventh Army front, members of the veteran 42d Hospital Train were notified that they were awarded the Meritorious Service Unit Plaque for "outstanding devotion to duty." The train is commanded by Major Samuel S. Gordon, Louisville, Ky., and the chief of medical service is Capt. Harold F. Goulston, New Bedford, Mass. The citation reveals that the 42d was the first hospital train to operate in southern France after the August 15 landing on the Riviera and was in continuous operation through the campaign which routed the Germans from southern and central France and on into Germany. In this period they carried 14,727 patients in forty-four round trips over a distance of 25,000 miles, as well as carrying 1,370 medical personnel and many tons of medical supplies to the Seventh Army.

Prior to the invasion of southern France the 42d operated in Italy, where it was cited by Major Gen. Arthur R. Wilson, then commanding general of the Peninsular Base Section, for evacuating wounded members of the American Fifth and British Eighth armies to rear areas. In North Africa the train took a direct part in the Sicilian campaign, receiving wounded by air evacuation at Constantine in Algeria. For services there the nurses of the unit were cited by the commanding general of the Mediterranean Base Section.

The 42d Hospital Train was activated on June 1942. Three fourths of present personnel have been with the unit since its activation at Camp Rucker, Alabama. After further training at Fort McPherson near Atlanta, Ga., the staff proceeded to North Africa, arriving there in April 1942.

NEW ARMY GUIDE FOR INDUSTRIAL MEDICAL PROGRAM

The Preventive Medicine Service, Office of the Surgeon General, recently announced the publication of a new manual prepared by the Occupational Health Division designed to serve as a guide in standardizing the medical program of dispensaries in army industrial installations. It is listed as ASF Manual M210 and is entitled "Operating Procedures for Industrial Dispensaries."

BEDSIDE DENTISTRY IN ARMY HOSPITALS

A portable dental unit is now being used in certain army hospitals to assure bedridden patients more complete dental care and speed convalescence. Plans are now under way to standardize this unit for all army general hospitals here. The portable dental unit carries equipment for a wide variety of dental operations from simple dental prophylaxis to treating fractured jaws and making complete new dentures.

ARMY AWARDS AND COMMENDATIONS

Lieutenant Colonel Elmer M. Smith

Lieut. Col. Elmer M. Smith, formerly of State Center, Iowa, was recently awarded the Legion of Merit for "exceptionally meritorious conduct in the performance of outstanding services in Italy from April 1 to Sept. 15, 1944. Confronted with the responsibility of malaria control for the headquarters and seven groups of the 306th Fighter Wing, Lieutenant Colonel Smith, as wing surgeon, accomplished outstanding work in combating malaria. The area occupied by the flying fields of the wing were considered among the worst malaria districts in Europe, where 99 per cent of the local Italian population had had malaria at one time or another. Lieutenant Colonel Smith immediately organized a survey of the district and visited the swamps to investigate the possibility of draining them. By his hard and thorough work, tools, screening, extra repellent and freon bombs were immediately secured at a time when they were vitally needed. In order to oil and clean the scores of swamps and streams in the area before the summer months he adopted the use of airplanes and chemical warfare equipment for spraying large areas and the use of special plows for the digging of swamp drainage ditches. His capable organizing ability in making malaria surveys, in gathering tools and labor to drain the marshes and in instituting and advertising malaria discipline among troops assured the malaria control projects of success, thereby reflecting great credit on himself and on the Medical Corps of the Army of the United States." Dr. Smith graduated from the State University of Iowa College of Medicine, Iowa City, in 1935 and entered the service Oct. 1, 1940.

Captain Lal. D. Threlkeld

The Bronze Star was recently awarded to Capt. Lal. D. Threlkeld, formerly of Syracuse, N. Y., "for meritorious service in connection with military operations against an enemy of the United States in France, Belgium, Holland and Germany from Aug. 1, 1944 to Jan. 30, 1945. When his squadron spearheaded a drive into Brittany, France, Captain Threlkeld displayed great ingenuity and remarkable stamina in treating many cases while on the move and in caring for all the wounded until evacuation was practicable, so that fatalities were kept to a minimum. His thorough professional knowledge and personal interest in the welfare of every member of his unit have greatly contributed to the efficiency and morale of the squadron and reflect credit on Captain Threlkeld's character as an officer of the Medical Corps of the Army." Dr. Threlkeld graduated from the University of Oklahoma School of Medicine, Oklahoma City, in 1940 and entered the service in June 1942.

Lieutenant Colonel H. D. Chalke

The United States of America Typhus Commission Medal was recently awarded to Lieut. Col. H. D. Chalke, assistant director of hygiene, Royal Army Medical Corps (British). The citation read "In connection with the work of the United States of America Typhus Commission during the epidemic of typhus fever in Naples and southern Italy in the winter of 1943-1944, Colonel Chalke had heavy responsibilities for the extension and application of typhus control measures pertaining to British troops and involving civilians in areas under British control. A particularly important part of these activities, carried out by him with notable success under the most difficult conditions, was the disinfection of refugees entering Italy from across the Adriatic. The services rendered by Colonel Chalke were an essential element in preventing spread of typhus in southern Italy."

Major Ira Teicher

Major Ira Teicher, formerly of Brooklyn, was recently awarded the Bronze Star. The citation accompanying the award read "for meritorious service in action during the period Jan. 25, 1945 to Feb. 6, 1945. Commanding the —— Portable Surgical Hospital, Captain Teicher performed 211 operations, 145 of which were in a three day period of continuous work. The combination of surgical skill and administrative ability exhibited by Captain Teicher under extreme conditions reflects great credit on himself and the armed forces of the United States." Dr. Teicher graduated from Cornell University Medical College, New York, in 1936 and entered the service in June 1942.

Captain Roy S. Averill

The Silver Star and an Oak Leaf Cluster were recently awarded to Capt. Roy S. Averill, formerly of Canonsburg, Pa., for gallantry. First cited for his heroism at Maknassey in March 1943, when his battalion was attacking a strongly fortified point, for which he was presented the Silver Star, Captain Averill in January 1944 near Cassino performed the action winning him the Oak Leaf Cluster in lieu of a second Silver Star. He carried three units of blood plasma through two unmarked mine fields under artillery fire and direct observation and administered treatment under fire, after which he helped the wounded men to the battalion aid station. Dr. Averill graduated from Western Reserve University School of Medicine, Cleveland, in 1940 and entered the service in July 1941.

Captain Edward O. Groeber

Capt. Edward O. Groeber, formerly of Brooklyn, was recently awarded the Bronze Star for meritorious service in combat from May 21 to 25, 1944, in Italy. The citation reads "With great efficiency Captain Groeber supervised the establishment and maintenance of lines of evacuation, over trackless stretches of mountains, using with great ingenuity mules and untrained Italian soldiers, as well as regularly assigned litter bearers. At the same time he rendered personally the highest degree of professional medical and surgical care." Dr. Groeber graduated from Long Island University College of Medicine, Brooklyn, in 1931 and entered the service June 19, 1942.

Captain James Gordon

Special commendation was recently extended to Capt. James Gordon, formerly of New York and now with the 155th Station Hospital "somewhere in the South Pacific," for splendid assistance rendered by his generous, willing and professionally excellent contribution to the dermatologic section of his unit. "By his professional ability and his eagerness to cooperate, this officer has set a high standard and has reflected credit on himself, his profession and his organization," the commendation read. Dr. Gordon graduated from New York University College of Medicine, New York, in 1929 and entered the service Aug. 18, 1942.

Captain Benjamin L. Falcone

A Certificate of Merit was recently awarded to Capt. Benjamin L. Falcone, formerly of Bridgeport, Pa. The citation read "From May 25, 1944 to June 29, 1944, as a medical officer with the First Army Medical Detachment, Captain Falcone landed on the continent on D day plus two and rendered valuable service in the treatment of large numbers of Allied and enemy casualties under difficult and trying circumstances." Dr. Falcone graduated from Hahnemann Medical College and Hospital of Philadelphia in 1936 and entered the service Sept. 3, 1942.

Captain William S. M. Ling

The Bronze Star was recently awarded to Capt. William S. M. Ling, formerly of New York, for his heroism on the Anzio beachhead in Italy. Dr. Ling, a physician of Chinese extraction, interned at Misericordia Hospital, Manhattan, and served in North Africa, Tunisia, Salerno and northern Burma as well as in Italy. He graduated from the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, in 1940 and entered the service Sept. 1, 1941.

Captain Donald W. Cheff

Capt. Donald W. Cheff, formerly of Wilmington, Del., was recently awarded the Bronze Star for heroic achievement in action during the Leyte campaign. He is company commander of the medical battery of the famed 77th Infantry Division, which also participated in the invasion of Guam. Dr. Cheff graduated from the University of Nebraska College of Medicine, Omaha, in 1937 and entered the service June 20, 1942.

MEDICAL ADMINISTRATIVE CORPS OFFICERS

Typical illustrations of the heroic part being played by Medical Administrative Corps officers in this war is found in the recent citations which name Lieut. Paul F. Kerkhoff and Lieut. Allen E. Meeks for their gallant actions under fire.

Lieutenant Kerkhoff, Cincinnati, was awarded the Silver Star for his heroism with the 45th Armored Medical Battalion of the 3d Armored Division during the Ardennes breakthrough in December. One ambulance was knocked out and the medical supply trucks were isolated. Lieutenant Kerkhoff organized a group that went through heavy fire to rescue the trucks, which contained valuable life-saving cargo.

Lieutenant Meeks, San Bernardino, Calif., was awarded the Bronze Star for his service as assistant battalion surgeon. "In many instances," the citation reads, "this diligent officer risked his life in evacuating the wounded while exposed to heavy, small arms, mortar and artillery fire. His aggressive, energetic actions and untiring devotion to duty saved the lives of many men."

The work of the Medical Administrative Corps officers is not restricted to the combat zones. They handle administrative work in almost every phase of the Medical Department's activities, thereby permitting doctors to confine most of their activities to professional duties. The growth in the past three years of the Medical Administrative Corps from a strength of 75 to 17,000 is an indication of the extent of their help to the Medical Corps.

RATE OF RECOVERY FROM CHEST WOUNDS

In a recent release from the War Department, Major Gen. Norman T. Kirk, Surgeon General of the Army, reported that the rate of recovery from chest wounds is triple that of the first world war. The death rate of wounded men who lived long enough to reach surgery in the first world war was 24 per cent. Now it is 8, and this low rate has been achieved in spite of the fact that chest wounds are more serious in this war because of the increase in bomb fragments. The teams of young surgeons on the battle lines believe that if the wounded man can be got alive to an evacuation hospital, the surgical station closest to the front lines, the chances are that he will live.

ARMY DOCTORS TO CONSERVE X-RAY FILM

According to the Office of the Surgeon General, Army Medical Officers have been ordered to conserve x-ray films and photographic paper because of serious civilian and military shortages of these materials. Medical case histories will continue to be prepared on all troops being redeployed, but routine chest x-rays will not be made. This step will not be necessary, the Office of the Surgeon General explained, because chest x-rays were made of these men when they went overseas and the Army has kept a critical eye on them ever since. However, if the redeployment examination indicates tuberculosis or any other chest disease, an x-ray will be made promptly.

ARMY HAS NEW HEALTH EDUCATION UNIT

A new health education unit was recently set up as part of the Preventive Medicine Service, Office of the Surgeon General, U. S. Army, to develop educational material for the various divisions of the Preventive Medicine Service. Capt. Granville W. Larimore is chief of the new unit.

MERITORIOUS SERVICE PLAQUE AWARDED

The 1777th Service Command Unit, Schick General Hospital, Clinton, Iowa, was recently awarded the Meritorious Service Unit Plaque for "superior performance and devotion to the hospital duties performed during the last sixteen months."

NAVY

NAMED HEAD OF MUSEUM COMMITTEE

Rear Admiral Harold W. Smith, chief of the research division of the Bureau of Medicine and Surgery, was recently designated chairman of a Medical Museum Committee and curator for the medical department in conformity with the projected plan for establishment of a naval museum in Washington. The appointment was made by Vice Admiral Ross T. McIntire, Surgeon General of the Navy. The Medical Museum Committee is responsible for the selection, collection, preparation and preservation of trophies, relics, pictures, models, dioramas and other materials of historical interest for exhibit in the contemplated naval museum in Washington.

NAVAL HOSPITAL HEADS MAY AWARD PURPLE HEART

The Secretary of the Navy recently authorized the presentation of the Purple Heart award by medical officers in command of all hospitals within the continental limits in order to eliminate delay between time of wound and award presentation. In addition, fleet commanders are authorized to delegate authority to award the Purple Heart "to commanding officers of such hospital ships, advance base or other hospitals within their commands as they may deem necessary for this purpose."

HISTORY OF PSYCHIATRY

Capt. Forrest M. Harrison, chief of the neuropsychiatric division of the National Naval Medical Center, Bethesda, Md., was recently ordered to the Bureau of Medicine and Surgery on a special assignment to write the history of psychiatry in the Navy in World War II.

NAVY AWARDS AND COMMENDATIONS

Captain Rolland R. Gasser

Capt. Rolland R. Gasser, formerly of Brooklyn, was recently awarded the Bronze Star "for meritorious service to the government of the United States as medical officer in command of a fleet hospital in the South Pacific area from March 31, 1944 to April 7, 1945. During this period Captain Gasser displayed exceptional ability in handling the many detailed medical problems which arose and worked tirelessly to establish and maintain excellent operating conditions throughout his command. By his initiative and thorough knowledge of medical administration he effected an efficient hospital service for the sick and wounded in the South Pacific and evacuees from adjacent areas. His leadership and professional skill were in keeping with the highest traditions of the United States Naval Service." Dr. Gasser graduated from Jefferson Medical College of Philadelphia in 1914 and has been in the service since June 11, 1917.

Lieutenant Commander Gerald O. Poole

Lieut. Comdr. Gerald O. Poole, formerly of Lindamere, Del., was recently cited by Admiral Harold R. Stark. The citation accompanying the award read "Your performance of duty prior to and during the invasion of France on June 6, 1944 has been brought to my attention. As senior medical officer at a U. S. naval advanced amphibious base your professional skill was responsible for averting a serious delay in training programs and preparations for the invasion. When, shortly before D day, food poisoning broke out involving in varying degrees some 500 officers and men of both base and small boat personnel,

your untiring devotion in caring for these men and your thorough analysis of the cause of the outbreak enabled all personnel to resume their duties quickly. For your professional skill and your devotion to duty you are hereby commended. This commendation carries with it the privilege of wearing the commendation ribbon." Dr. Poole graduated from Hahnemann Medical College and Hospital of Philadelphia in 1931 and entered the service Oct. 19, 1942.

Lieutenant Commander Clinton P. O'Connell

The Navy and Marine Corps Medal was recently presented to Lieut. Comdr. Clinton P. O'Connell, formerly of Paterson, N. J., for "heroism displayed in attending the wounded and evacuating casualties while under enemy fire during amphibious operations in the Southwest Pacific Area from April 1944 to July 1944. A member of the surgical unit of the Seventh Amphibious Force accompanying assault waves, Lieutenant Commander O'Connell, by his courage and skill in providing medical care, helped save many lives and aided in making possible the transportation of casualties over greater distances than ever attempted previously." Dr. O'Connell graduated from Columbia University College of Physicians and Surgeons, New York, in 1932 and entered the service July 28, 1941.

Lieutenant James C. Owens

The Bronze Star was recently awarded to Lieut. James C. Owens, formerly of Beloit, Wis., who was cited for his heroism and his outstanding professional ability during an amphibious assault operation against Saipan and Marianas islands. Through his efforts and under adverse conditions when other medical units were disorganized, lives of many casualties were saved. Dr. Owens graduated from Marquette University School of Medicine, Milwaukee, in 1942 and entered the service March 8, 1943.

Commander John F. Woodward Jr.

The Navy Commendation Ribbon for outstanding performance of duty as senior medical officer at the U. S. Naval Dispensaries at Oran and Naples was recently awarded to Comdr. John F. Woodward Jr., formerly of New York. The citation accompanying the award read, in part, "Your thorough and untiring efforts contributed materially to the maintenance of a high standard of health and well being among the personnel of the fleet and supporting shore establishments and to the prompt and efficient handling of battle casualties during the amphibious invasions of Italy and southern France." Dr. Woodward graduated from the University of Virginia Department of Medicine, Charlottesville, in 1928 and entered the service in May 1942.

Lieutenant Commander Victor S. Falk

The Silver Star was recently awarded to Lieut. Comdr. Victor S. Falk, formerly of Wauwatosa, Wis., for treating wounded Marines under fire on Guadalcanal. The citation read, in part, "for conspicuous gallantry and intrepidity while serving with the First Marine Aircraft Wing during action against enemy Japanese forces on Guadalcanal, Solomon Islands, on the night of Oct. 13-14, 1942." Dr. Falk graduated from the University of Wisconsin Medical School, Madison, in 1939 and entered the service Nov. 28, 1941.

Lieutenant Robert M. Collins

The Navy and Marine Medal was recently awarded to Lieut. Robert M. Collins, formerly of Council Bluffs, Iowa, for "distinguishing himself by meritorious achievement and service in connection with operations in the Southwest Pacific as a member of the surgical unit of the 7th Amphibious Force during the period of April 1944 to July 1944." Dr. Collins graduated from the University of Nebraska College of Medicine, Omaha, in 1931 and entered the service Sept. 7, 1942.

MISCELLANEOUS

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service:

(Continuation of list in THE JOURNAL, May 12, page 137)

ILLINOIS

Columbus Hospital, Chicago. Capacity, 180; admissions, 3,501. Reverend Mother M. Grace, R.N., Superintendent (2 interns).

Mother Cabrini Memorial Hospital, Chicago. Capacity, 144; admissions, 3,931. Mother Agnes, R.N., Superintendent (2 interns).

Oak Park Hospital, Oak Park. Capacity, 182; admissions, 5,479. Sister St. Colette, Superintendent (intern, July 1).

KANSAS

University of Kansas Hospitals, Kansas City. Capacity, 400; admissions, 7,606. Dr. J. Harvey Jennett, Medical Director (resident—anesthesia; assistant resident—surgery, July 1, disqualified for military service).

KENTUCKY

Louisville General Hospital, Louisville. Capacity, 587; admissions, 9,971. Dr. John Walker Moore, Medical Director (resident—medicine; 2 assistant residents—surgery).

MASSACHUSETTS

Boston City Hospital, Boston. Capacity, 2,537; admissions, 35,559. Dr. James W. Manary, Medical Director (resident—dermatology, July 1, disqualified for military service).

MISSOURI

St. Louis City Hospital, St. Louis. Capacity, 1,104; admissions, 14,098. Dr. Leo J. Wade, Medical Director (resident—pathology, July 1, disqualified for military service).

NEW YORK

Herman M. Biggs Memorial Hospital, Ithaca. Capacity, 250; admissions, 204. Dr. N. Stanley Lincoln, Superintendent (residents—tuberculosis and thoracic surgery).

St. John's Riverside Hospital, Yonkers. Capacity, 220; admissions, 4,429. Mr. S. Chester Fazio, Superintendent (4 interns, February 1, 1946).

OHIO

Glenside Hospital, Cleveland. Capacity, 135; admissions, 3,411. Mr. A. B. Harris, Superintendent (resident—mixed, disqualified for military service).

TENNESSEE

Nashville General Hospital, Nashville. Capacity, 337; admissions, 6,586. Mr. T. F. Connally, Administrator (intern, July 1).

UTAH

St. Mark's Hospital, Salt Lake City. Capacity, 238; admissions, 4,838. Mrs. Olive V. Wardrop, Superintendent (intern).

WARTIME GRADUATE MEDICAL MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

California

U. S. Naval Air Training Station, San Diego: Rh Factor, Capt. George Macer, June 1.

Camp Haan, ASF Regional Hospital, Riverside: Thoracic Surgery, Dr. John Jones and Lieut. Comdr. J. E. Dailey, June 5.

Torney General Hospital, Palm Springs: Management of Simple Skin Diseases, Lieut. Col. Everett R. Seale, June 5.

AAF Regional Hospital, Santa Ana Army Air Base: Blood and Blood Substitutes, Lieut. Comdr. W. M. Cashman, June 5.

Station Hospital, Camp Cooke, Lompoc: Internal Derangements of the Knee, Dr. John C. Wilson, June 6.

Hoff General Hospital, Santa Barbara: Internal Derangement of the Knee, Dr. John C. Wilson, June 6.

U. S. Naval Hospital, San Diego: Diabetes, Drs. H. F. West and J. W. Sherrill, June 7.

Birmingham General Hospital, Van Nuys: Spondylitis, Major A. J. Present, June 13.

U. S. Naval Hospital, Santa Margarita Ranch: Surgery of Traumatic Urinary Tract, Lieut. Comdr. John B. Wear, June 14.

U. S. Naval Hospital, Corona: Diabetes, Drs. H. F. West and J. R. Sherrill, June 14.

U. S. Naval Air Training Station, San Diego: Dentistry, Comdr. E. P. Garvey (DC).

ORGANIZATION SECTION

Washington Letter

(From a Special Correspondent)

May 21, 1945.

Drug Cartels and the National Health

Following a warning by Wendel Berge, assistant U. S. attorney general, that drug cartels and monopolies have seriously retarded national health, a House subcommittee investigating aid to the physically handicapped has proposed war on monopolies and cartels in industries relating to health. Elimination of such monopolies, said Mr. Berge, would be "one of the most constructive tasks of our generation." He said that the "time had come for Congress to consider the cartel problem in all its aspects." He asserted that monopoly practices in the medicinal and pharmaceutical field led to suppression of research data, prevented introduction of improved processes and products and kept outsiders from engaging in research. He declared that "because of artificial and exorbitant price structures the low income groups in particular have been unable to obtain the benefits of advances in science or better physical aids." He stated, among his charges, that: 1. Thirty-four thousand Americans need spectacles and cannot buy them because of controlled prices. 2. Despite an annual world death of more than 3 million people, 500 million sufferers from malaria were dependent in prewar days on quinine obtained from a few thousand acres of cinchona trees in Java. 3. Production and distribution of all types of surgical supplies is controlled by a monopoly group. 4. The public has been forced to pay "excessive and arbitrary prices by a monopoly controlling the vitamin D industry." 5. A "small ring of producers" of insulin "exploited" 2 million sufferers of diabetes in this country by "imposing arbitrary prices and unreasonable conditions of distribution." 6. A plastic, methyl methacrylate, was sold to industrial concerns for 85 cents a pound and to dental users for $45 a pound, although "the dental profession soon learned that there was no difference in the material." 7. German I. G. Farben-Industrie once attempted to sell the secret of Bayer 205, a cure for sleeping sickness, for restoration of Germany's lost African colonies.

The subcommittee also heard Henry Miller, director of the Trade Practices Conference of the Federal Trade Commission, and R. P. Whiteley of the FTC legal staff, on advertising of drugs, eye glasses and hearing aids.

Lay Control of Veterans Administration Hospitals

Representative Walter Judd of Minnesota, a physician, has charged that Veterans Administration hospitals are too much controlled by laymen, which he says will "inevitably develop whenever and wherever government bureaus under nonmedical men tell doctors how to practice." It has been pointed out that the House Veterans Committee under Chairman John Rankin of Mississippi, now investigating the Veterans Administration, does not include any physicians, fifteen of the twenty-one members being lawyers. This fact has been criticized editorially, one paper stating that none of the members have any obvious qualifications "to pass judgment on highly technical questions of medical expertness or hospital management. Picture the indignation among Congressmen if a committee of doctors should undertake to dissect their performance as legislators." Also criticized were the Rankin sponsored visits to veterans' hospitals, which were described as "Cook's tours." It has also been pointed out that Representative Rankin is the strongest Congressional defender of Veterans Administrator Brigadier General Hines. The latest development in the hearing is a contempt citation by the committee against a *New York* reporter for refusal to tell the names of Veterans Administration officials who supplied information used in his articles criticizing veterans' hospital care. President Truman has denied that there will be a shake-up in the agency or that he will replace General Hines by former Senator Bennett Champ Clark of Missouri.

Institute at Ann Arbor for Placement of Handicapped

Medical, industrial, social welfare and labor groups will be represented at the five day institute for discussion of the War Manpower Commission's selective placement program for the handicapped at the University of Michigan, Ann Arbor, May 28 through June 1. An important phase will be panel discussions on placement of returning veterans who have suffered severe service connected disabilities. The conference will lay the groundwork for an expanded program to disabled through local USES offices. Among the speakers will be Holland Hudson, director of rehabilitation for the National Tuberculosis Association; Dr. W. C. Strang of the Civil Service Commission; Dr. F. J. Brady of the U. S. Public Health Service; Dr. Raymond Hussey, dean of the School of Occupational Health, Wayne University; Dr. Carl Peterson, Secretary, Council on Industrial Health, American Medical Association; Dr. Clarence Selby, medical director of General Motors; Dr. H. L. Krieger, medical director of the Ford Motor Company; Capt. H. H. Montgomery of the Bureau of Medicine and Surgery, U. S. Navy, and Col. E. G. Solomon of Selective Service.

Amputation Cases in Army Hospitals

Surg. Gen. Norman T. Kirk announces that on May 1 there were approximately 11,000 amputation cases in army hospitals in this country, including cases already discharged. He said there are still no "basket cases," a term used to describe a person who has lost both arms and both legs. There are 6 amputees who have lost three extremities and 1 case of a nonbattle casualty who lost part of four limbs through freezing after an airplane crash. About 5 per cent of the patients have lost more than one limb, General Kirk said. Of these, 77 per cent are leg amputations, of which 49 per cent are below the knee and about 28 per cent above the knee. Half of the arm cases are below the elbow. Almost 4,000 of the amputees have been discharged to civilian life. Some soldiers are remaining in the service and have been assigned to assist in training other amputees.

Red Cross to Increase Personnel in the Pacific

In a statement issued at Pearl Harbor and received here, Basil O'Connor, national chairman of the Red Cross, said that the organization will double its facilities in the Pacific and increase to 60,000 nurses and 32,000 other workers within a year. O'Connor is en route to the Philippines for discussions with Gen. Douglas MacArthur and later with Fleet Admiral Chester W. Nimitz. "The Red Cross is now working on terra firma in Europe, but here we must leap forward from island to island," he said.

Capital Notes

Reports indicate that returns in the national cancer campaign to raise $5,000,000 are exceeding expectation but that continued support is required.

Despite reports of an anticipated increase in malaria through return of men from disease infected war areas, the Maryland Bureau of Communicable Diseases reports that it has experienced no such increase.

Chairman Bilbo of the Senate District Committee has introduced in the Senate a bill to strengthen District of Columbia contagious disease control. A companion measure was placed before the House earlier by Representative McMillan, Democrat of South Carolina.

Although nineteen blood donor centers in the country were to close May 19, the District of Columbia center will continue with renewed effort, reports Red Cross National Chairman O'Connor.

Bureau of Information

COUNTY SUMMARY SHEETS FROM KENTUCKY, MISSOURI AND NEW MEXICO

Kentucky, through Dr. P. E. Blackerby, secretary of the Kentucky State Medical Association, Missouri, through Mr. T. R. O'Brien, executive secretary of the Missouri State Medical Association, and New Mexico, through Dr. L. B. Cohenour, secretary of the New Mexico Medical Society, have returned completed county summary sheets.

Kentucky

County [1]	Principal Cities [2]	Population	Physicians Under 65	Persons per Physician	Persons per Telephone [3]

1. Bureau of Census, estimated population 1943.
2. Bureau of Census, population 1940.
3. Based on 1940 figures, American Telephone and Telegraph Company.

Data from five representative counties of each state are presented in the accompanying table. The column giving the number of persons per telephone is used as one index of the economic status of the area. Many physicians over 65 years of age are carrying on large practices and are doing much to maintain the health of communities. They are not included in computing physician population ratio, however, as the future needs of the communities will be largely dependent on younger physicians.

A current knowledge of needs of communities for doctors is essential if adequate help is to be given veteran medical officers in their problems of medical practice. These needs can be indicated on the summary sheets under "Remarks" by the state and county secretaries and are then available to inquiring medical officers. Frequent reports from state and county medical societies about needs of communities for doctors will help maintain current files and will increase the service of the Bureau.

With the information available on a completely filled out summary sheet, it is readily possible for an interested medical officer to make an initial selection of areas in which he might like to practice. Since vacancies are held open in many communities for doctors now in military service, further investigation by direct correspondence with state and county medical societies will always be necessary to insure an accurate report of the needs of individual communities.

Medical Legislation

MEDICAL BILLS IN CONGRESS

EMIC Program

An additional appropriation of $44,189,500 will be made available for the EMIC program by H. R. 3199, a bill making appropriations for the Department of Labor, the Federal Security Agency and related independent agencies for the fiscal year ending June 30, 1946. In its report on the bill, which has now passed the House, the Committee on Appropriations referred to prior efforts to prevent what it described as "discrimination between persons licensed under state law to practice obstetrics." The committee thought that some progress had been made in "eliminating the discrimination" but suggested an additional proviso to the language inserted by the committee last year, as follows: "Provided further, That a state plan shall include standards for professional services prescribed by the state health agency within the limitations contained in this title and such standards so prescribed shall be approved by the chief of the Children's Bureau." On motion of Representative Judd, Minnesota, this proviso was amended to read "Provided further, That any state plan which provides standards for professional obstetric services in accordance with the laws of the state shall be approved by the chief of the Children's Bureau."

Veterans Administration

Representative Miller, Nebraska, has introduced H. R. 3254 to authorize the furnishing in private facilities of medical and hospital treatment to certain veterans. This will be accomplished by defining the term "Veterans Administration facility" as used in the existing law to include any private facility for which the Administrator of Veterans' Affairs may deem it necessary to contract in order to provide medical and hospital treatment (1) in emergency cases; (2) for veterans of any war, in any case where neither a facility under the exclusive jurisdiction of the Veterans Administration nor a government facility utilized by the Veterans Administration is within a reasonable distance of the place of residence of the veteran; (3) for women veterans of any war, and (4) for veterans of any war in the territories and possessions.

Food and Drugs

A bill introduced by Representative Lea, California, H. R. 3266, proposes to amend the Federal Food, Drug and Cosmetic Act by providing for the certification of batches of drugs composed wholly or partly of any kind of penicillin or any of its derivatives. The language of the bill is similar to that of the existing law safeguarding the purity of insulin.

U. S. Employees' Compensation Act

A subcommittee of the Senate Committee on Education and Labor held a hearing, May 16, on S. 178, a bill to permit chiropractors to treat the beneficiaries of the U. S. Employees' Compensation Act. Only witnesses who supported the bill testified, including the sponsor of the bill, Senator Murdock, Utah, Representative Tolan, California, who has introduced a companion bill in the House, representatives of the National Association of Letter Carriers, of the National Federation of Post Office Clerks, of the Rural Mail Carriers' Association, and the Director of Education, National Chiropractic Association, John J. Nugent, D.C. Witnesses in opposition to the bill will be heard on a later date. The following members of the Senate Committee on Education and Labor comprise the subcommittee: Senators Fulbright, Arkansas, chairman; Walsh, Massachusetts; Chavez, New Mexico; Smith, New Jersey, and Morse, Oregon.

STATE LEGISLATION

Alabama

Bill Introduced.—H. 148 proposes to appropriate $150,000 annually for the next biennium to the state board of health for acquiring and distributing whole blood and blood plasma to persons in need thereof.

Florida

Bills Introduced.—S. 435, to amend the medical practice act, proposes, among other things, to make it unlawful (1) for any physician to fail or neglect to register by January 1 annually and to provide a penalty of $50 for such an offense; or (2) for any person to sell or fraudulently obtain or furnish any medical diploma, license, record or registrations or to practice medicine under such fraudulent credentials, or advertise to practice medicine under a name other than his own. S. 436, to amend the medical practice act, proposes (1) to make it the specified duty of the state board of health, of all peace officers and of all prosecuting attorneys to enforce the provisions of the act and (2) to authorize the state board of medical examiners to proceed by injunction to restrain any continued violation of the act. H. 664 proposes to prohibit the operation of a private nursing home in counties having a population of from 65,000 to 74,000 unless licensed to do so by the state board of health.

Illinois

Bills Introduced.—S. 466 and H. 649, to amend the medical practice act, propose that students matriculating or entering on a course of study of any system or method of treating human ailments without the use of drugs or medicines and without operative surgery during the years 1940 to 1947, inclusive, shall be entitled to examination for licensure if they have graduated from a healing art school and if the course of instruction pursued therein has not been less than thirty-two months. Under the present law the course of instruction must not be less than thirty-six months.

Massachusetts

Bills Introduced.—S. 551 proposes to create a special commission to study the advisability of establishing a state university, including a medical and dental school. S. 554, to amend the medical practice act, proposes that the authority approving medical schools shall consist, in addition to its present members, of an osteopathic member of the board of registration in medicine and a layman. H. 1905 proposes to create a special commission of two senators, four representatives and three persons appointed by the governor to investigate all institutions, other than educational, maintained by the commonwealth with respect to the conduct of such institutions, the adequacy of their facilities and such other matters as the commission may deem advisable. H. 1923 proposes to provide what is designated as a voluntary system for the payment of hospital, surgical operation, sickness and bodily injury and maternity benefits to employees.

Texas

Bills Introduced.—H. Con. Res. 34 proposes to create a state commission to make a comprehensive survey of existing hospital facilities and the need, if any, for additional hospitals, clinics and health services and to serve as the state agency for executing the hospital program that may be enacted by the federal Congress. S. 216 proposes to require the state department of health to survey hospital facilities, health centers, clinics and related public health needs as provided for in S. 191 now pending before the federal Congress. The bill proposes to authorize the board of health to make and/or approve applications for funds as may be provided in any future federal law.

Official Notes

DOCTORS LOOK AHEAD

Radio broadcasts by the American Medical Association under the title Doctors Look Ahead and other titles have emphasized medical progress. There remains however the unfinished business which confronts the medical profession about which little is said. Doctors Look Ahead therefore will broadcast a program devoted exclusively to looking ahead at the challenge of tomorrow, at the unfinished business, at the progress that has not been made. This program will be broadcast May 26 and the guest speaker will be Dr. Morris Fishbein, Editor of THE JOURNAL.

Other programs in the Doctors Look Ahead series scheduled in the next four weeks are as follows:

June 2. Fit to Live: A program devoted to the topic of fitness as distinguished from health and illustrating the nation's needs and its opportunities for greater efficiency through greater physical fitness.

June 9. They Shall Hear Again: A program devoted to the needs of the hard of hearing and indicating new opportunities for them through the use of hearing aids, lip reading, medical treatment and occasionally surgery. Guest speaker, Howard A. Carter, B.S. in M.E., Secretary of the American Medical Association Council on Physical Medicine.

June 16. Home Was Never Like This: A program devoted to the possibilities of the American health resort or spa in the treatment of disease. Guest speaker, Dr. Walter S. McClellan, chairman of the American Medical Association Committee on Health Resorts, speaking from New York.

June 23. Postwar Doctor: Problems in medical education and their influence on the public health. Guest speaker, Dr. Victor Johnson, Secretary of the American Medical Association Council on Medical Education and Hospitals.

When no speaker is announced the summary will be given by Dr. W. W. Bauer, Director of the Bureau of Health Education. Doctors Look Ahead is heard on one hundred and twenty-three stations of the National Broadcasting Company network each Saturday at 4 p. m. Eastern War Time (3 p. m. Central War Time, 2 p. m. Mountain War Time and 1 p. m. Pacific War Time). Beginning May 26 the program will be heard at 4:30 p. m. Eastern War Time and corresponding times in other time zone areas.

Woman's Auxiliary

New Jersey

A symposium on Postwar Problems of Community Health was recently sponsored by the Woman's Auxiliary to the Essex County Medical Society. Lieut. Col. Stuart Z. Hawkes, chief of Surgical Service, Army Air Force Convalescent Center at Mitchel Field, was guest speaker.

Ohio

The Hamilton County auxiliary has had three forum meetings since October, the subjects being "Juvenile Delinquency," "Health in Our Schools" and "Global Medicine."

The Marion County auxiliary recently purchased a new incubator and bed oxygen unit for the City Hospital.

Members of the Chillicothe auxiliary were recently entertained by Miss Alice Myers, who gave a travel talk on Mexico City and Guatemala. The auxiliary has planned a bridge party and rummage sale to raise funds for purchasing an incubator for the Chillicothe Hospital.

The auxiliary to the Columbus Academy of Medicine sponsored a two part discussion, one devoted to "Health Examinations for School Children and Employees" and the second to the Kellogg school education plan. The superintendent of schools, several school nurses and the coordinator of school health projects took part in the discussion.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

District Meeting.—The First Councilor District Medical Society held its eighty-fifth semi-annual meeting at Jonesboro Country Club, May 15. The speakers were:

Dr. Allie C. Kolb, Little Rock, War Neurosis in Returning Soldiers.
Dr. Joseph F. Shuffield, Little Rock, Discussion of Medical Legislation.
J. P. Womack, Jonesboro, A Layman Looks at the Doctor.

CALIFORNIA

Veterans Studying Professions.—Forty-one veterans were studying medicine, dentistry and pharmacy on the San Francisco campus of the University of California May 4, according to the university *Clip Sheet*. Thirty-eight of the veterans were registered under the G. I. Bill of Rights and three are under Public Law 16, which provides scholarships for veterans in need of rehabilitation. Ages vary from 20 to 44 years.

Prevalence of Diphtheria.—The report of 28 cases and 5 deaths from diphtheria in San Francisco for 1945 indicates an upward trend, according to Dr. Jacob C. Geiger, director of public health of the city and county of San Francisco. Of the 28 cases, 11 were from the military forces and had not been immunized. Ten were in adults ranging from 24 to 72 years, none of whom had ever been immunized. Of the 11 children affected 6 were newcomers to the community and had not been immunized. Of the 5 remaining children, 4 being newcomers, there was some history of immunization from one to fourteen years before the disease occurred in this group. Dr. Geiger points out that of these 5 none had ever been checked by the Schick test as to the efficiency of the immunization and no "booster" injections were given. There was no common source of the infection of these cases, except in one family, the source not having been traced up to May 7. There was no concentration of cases in any area or in any school. From 1941 to 1945 about 10 cases a year was the average, less than 1 a month, generally in adults with none of these immunized. Up to this year one could further consider the disease to be not one of childhood, Dr. Geiger stated.

CONNECTICUT

Student Members.—One hundred and sixty-seven applications for membership as student members have been approved by the council of the Connecticut State Medical Society. This is the first time that the student members have been included as special members of the society, an action voted by the house of delegates (THE JOURNAL, Dec. 16, 1944, p. 1039).

FLORIDA

Changes in Health Officers.—Dr. Frank V. Chappell, Tampa, has been appointed director of the Hillsborough County Health Department, succeeding Dr. Charles W. Pease, Tampa, who was named epidemiologist of the department.——Dr. Kolbein L. K. Waering, Jacksonville, director of the Duval County Department of Health, has resigned.——Dr. Smith L. Turner, Williston, has been named health officer of Levy County.——Dr. Joseph A. Markley, U. S. Public Health Service, has been appointed health officer of Duval County, succeeding Dr. Waering.

ILLINOIS

Changes in Status of Licensure.—The Illinois Department of Registration and Education on March 6 took the following action:

Dr. Lawrence T. Browning, formerly of Holden, W. Va., license revoked for conviction of violation of the National Motor Vehicle Act.
Dr. Oscar F. Roberts, Chicago, license revoked for conviction of violation of Internal Revenue Code.
Dr. Toros Sarkisian, formerly of Denver, license revoked for conviction in the Colorado courts of performing an abortion.

Personal.—Dr. W. W. Bauer, Director of the Bureau of Health Education, American Medical Association, Chicago, will deliver a talk before the Citizens' Public Health Association of St. Clair County in Belleville, May 22, on "Health for All People."——Dr. Edward B. Miller has been appointed health officer for district number 2 including counties of Boone, Lake and McHenry, with headquarters in Woodstock. Dr. Miller, who was recently in the medical corps of the Army of the United States, succeeds Dr. Fred O. Tonney.

New Society of Ophthalmology and Otolaryngology.—The Central Illinois Society of Ophthalmology and Otolaryngology was recently formed for the benefit of those practicing in these specialties in the central part of Illinois. Officers include Drs. Watson Gailey, Bloomington, president; Walter D. Stevenson, Quincy, and Stuart Broadwell Jr., Springfield, vice president, and William F. Hubble Jr., Decatur, secretary-treasurer. The membership is limited to 50 and is open to members of the national board or those eligible to membership in it. Three meetings a year will be held, the first of which was in Bloomington, April 21-22.

Chicago

The Maurice Lamm Blatt Memorial Fund.—Colleagues of the late Dr. Maurice Lamm Blatt on the pediatric staff of the Cook County Hospital are sponsoring the establishment of the Maurice Lamm Blatt Memorial Fund. Proceeds would be used to create either an annual prize for a resident or intern doing outstanding work in pediatrics or, if sufficient funds are forthcoming, a fellowship, scholarship or lectureship in pediatrics. Three categories have been designated for membership in the project: any amount up to $25, contributing membership; $25 or more, sustaining membership, and $100 or more, life membership. Checks should be made payable to Dr. Meyer A. Perlstein, chairman of the Maurice Lamm Blatt Memorial Fund, 185 North Wabash Avenue, Chicago 1.

Personal.—Dr. Herman L. Kretschmer, President of the American Medical Association, has been named chairman of a committee to raise funds to pay for transferring the 276 ton Louis Pasteur Memorial statute from Grant Park to the Medical Center district on the west side, newspapers reported May 14. Ray. McCarthy, president of the Medical Center Commission, said title to the memorial has been conveyed by the Chicago Park District Board. The Pasteur Memorial, a 51 ton statue on a 225 ton base, stands on the west lawn of the Chicago Natural History Museum.——Dr. Max Thorek will deliver the commencement address of the Iowa Wesleyan College, Mount Pleasant, Iowa, May 27, on "Medicine in a Mad World." Dr. Thorek will receive on this occasion the honorary degree of doctor of science.

Malcolm MacEachern Award.—The Johnson and Johnson Research Foundation has created an annual award at Northwestern University consisting of a silver medal and an honorarium of $250 to be known as the Malcolm T. MacEachern Award. The award honors Dr. MacEachern, associate director of the American College of Surgeons and director of the program in hospital administration at the school. The award was announced at a National Hospital Day celebration in the auditorium of the American College of Surgeons, May 12, simultaneously with an announcement of a five year grant of $75,000 to the program in hospital administration, including scholarships, also from the Johnson and Johnson Research Foundation, to supplement $15,000 granted two years ago. A renewal of scholarship grants by the American Hospital Supply Corporation was also announced. Since the program in hospital administration was started in September 1943, 113 students coming from seventeen states have enrolled in one or more of the nine new courses offered, in addition to taking background courses in other departments of the university. An advisory committee, board of consultants and faculty consisting of authorities in the hospital field assist in formulating policies of the program, conduct the courses and demonstrations and supervise the internships required before conferring degrees. Dr. Irvin Abell, Louisville, Ky., chairman of the board of regents of the American College of Surgeons, spoke on "The Significance of National Hospital Day, 1945."

KENTUCKY

Past President Honored.—Dr. John H. Blackburn, Bowling Green, was recently given a dinner in honor of his completion of forty-five years in the practice of medicine. Dr. Blackburn was councilor of the Kentucky State Medical Association from 1921 to 1928, when he was elected to the presidency.

Distinguished Service Medal.—The Kentucky State Medical Association is now accepting names for the distinguished service medal approved in 1944 to be awarded annually to one of its members. Any member of the association is eligible to be nominated by any other member as an applicant

for the medal. All names will be considered by the council of the association, three to be selected as being worthy and these three to be submitted to the house of delegates for final selection.

Sigma Alpha Affiliates with Alpha Epsilon Delta.—On April 29 Sigma Alpha, premedical fraternity of the University of Louisville, became affiliated with Alpha Epsilon Delta, national honorary premedical fraternity, on its installation as the Kentucky Alpha chapter. The initiation of eighteen active and three honorary members was conducted by Hugh E. Setterfield, Ph.D., associate professor of anatomy, Ohio State University, Columbus, and national president of the Alpha Epsilon Delta. Dr. Setterfield's subject at the banquet was "What Kind of Doctor?" Sigma Alpha was organized on March 29, 1933 at Louisville under the auspices of Alfred W. Homberger, Ph.D., professor and head of the department of chemistry and premedical adviser. Alpha Epsilon Delta was founded at the University of Alabama in 1926 and now includes thirty-four chapters.

Personal.—Dr. Percival Bailey, professor of neurology and neurologic surgery at the University of Illinois College of Medicine, was commonwealth visiting professor of neurology and neurologic surgery at the University of Louisville School of Medicine during the month of April.——James T. Lowe, Ph.D., has been appointed director of nutritional research for the Nestle's Milk Products, Inc., New York. Dr. Lowe has been research associate for the Wisconsin Alumni Research Foundation, Madison, Wis., for the past ten years.——Dr. Bohdan G. Giel, U. S. Public Health Service, has been temporarily assigned as health officer in Perry County.——Dr. William H. Smith was chosen president of the Boyle County Board of Health recently to succeed the late Dr. John D. Jackson, who had held the position for twenty-two years. Dr. Perry C. Sanders was elected secretary of the board and health officer of Boyle County for another two year term. He and Dr. Smith have also been members of the board for twenty-two years. All are of Danville.

MICHIGAN

County Society Creates Administration Plan.—The Calhoun County Medical Society has elected an active policy committee to direct and coordinate the administrative program of the society. Dr. Joseph E. Rosenfeld, Battle Creek, as chairman of the committee, will be in charge of all publicity; Dr. George A. Zindler, Battle Creek, as secretary is in charge of coordinating all postgraduate and postwar educational problems in the local hospitals for returning military members, including the raising of funds for the committee program. Dr. Carl G. Wencke, Battle Creek, will have charge of political medicine. Dr. Russell L. Mustard, Battle Creek, will develop plans for a central office and executive secretary and a central telephone agency. Dr. Duward L. Finch, Battle Creek, will have charge of the rehabilitation problems of members returning from war service as well as the responsibility of keeping in communication with them, sending bulletins and other useful information. Dr. Alpheus T. Hafford, Albion, is to coordinate all the activities in the county areas outside of Battle Creek.

Provision for Accident Care.—Effective May 1, new certificates greatly broadening the protection of enrolled physicians and their office employees were issued by Michigan Hospital Service and Michigan Medical Service. The new certificates make the hospital service virtually all inclusive for the average case and extend the surgical plan in all respects, including the addition of a provision for accident care. Certificates will be provided at a moderate increase in rates for the hospital protection and at no increase in rates for the surgical protection. The benefits show an increase in the number of full days' service from twenty-one to thirty for patients, the provision of the same amount of care for every disability rather than a limitation of care by the year, and the addition of such former "extras" as basal metabolism examinations, accident room care, physical therapy, extensive laboratory service and penicillin. Recent changes in the surgical benefit contract of the Michigan Medical Service include a $150 maximum providing for full surgical service for those conditions requiring multiple stage operations, such as tuberculosis and cancer. In maternity benefits the waiting period will apply only to childbirth and is reduced from ten to nine months. Miscarriage, ectopic pregnancy and the like will be covered from inception of the contract, while the former exception to self-inflicted injuries has been eliminated. Emergency surgical service in the outpatient department of the hospital will be provided for accidental injuries but will not include outpatient x-ray service. In addition, a special rider contract provides pathologic laboratory services to all subscribers to Michigan Hospital Service.

MINNESOTA

Personal.—On April 1 Dr. Donald W. Pollard, who has been absent from the superintendency of Minneapolis General Hospital because of war leave, was to return to the Minneapolis General Hospital, having been placed on inactive duty. Dr. Francis E. Harrington, formerly city health officer, has been acting superintendent since August 1942 (THE JOURNAL, Aug. 19, 1944, p. 1150).——Dr. Sidney A. Slater, superintendent of Southwestern Minnesota Sanatorium, Worthington, since 1919, will receive the honorary degree of doctor of science at the University of Richmond, Richmond, Va., April 27. He will be presented with a Phi Beta Kappa key which was previously awarded. Dr. Slater graduated at the University College of Medicine, Richmond, in 1909.

Airlines Contribute to Mayo Fund.—The Northwest Airlines gave $5,000 to the Mayo Memorial Fund recently as a tribute to the contributions of the Mayo Clinic to both wartime and peacetime aviation in pioneering scientific researches with especial attention to high altitude flying. The donation, voted by the company's board of directors, was accompanied by a resolution calling attention to the establishment by the state legislature of a research center at the University of Minnesota and emphasizing the "close collaboration of the Northwest Airlines with the Mayo Clinic for many years" (THE JOURNAL, January 13, p. 111). An announcement credits the work of the clinic before the war, in charge of Col. William R. Lovelace, M. C., now in charge of the Army Air Forces research center at Wright Field, Dayton, Ohio, and discusses the studies of the use of oxygen in high altitude flying in which the Northwest Airlines cooperated.

NEBRASKA

State Medical Election.—Dr. Earle G. Johnson, Grand Island, was named president-elect of the Nebraska State Medical Association at a meeting of the house of delegates in Lincoln, May 8. Dr. Charles McMartin, Omaha, is president.

Society News.—The Omaha-Douglas County Medical Society was addressed May 8 by Mr. J. W. Holloway Jr., Director of the Bureau of Legal Medicine and Legislation of the American Medical Association, Chicago, on "Trends in Federal Legislation" and Dr. Victor E. Johnson, Secretary, Council on Medical Education and Hospitals, American Medical Association, on "Postwar Problems and Plans in Medical Education."

National Broadcast Features Hospital Day.—Dr. Donald C. Smelzer, Philadelphia, president of the American Hospital Association, gave a special talk May 13 at Creighton Memorial St. Joseph's Hospital, Omaha, which was delivered over one hundred and twenty-three stations as a National Hospital Day feature. The talk was a part of the program "Your America," sponsored by the Union Pacific Railroad. The program also included an interview over the radio of Dr. Adolph Sachs, Omaha, medical director of the Union Pacific Railroad, with Ray Olson, Omaha radio newscaster. The official celebration was observed May 12 but the Sunday broadcast was a part of the program.

NEW · YORK

Retirements at Rochester University.—John R. Murlin, Ph.D., professor of physiology and director of the department of vital economics, University of Rochester School of Medicine and Dentistry, Rochester, will retire July 1. Dr. Edwin Fauver will retire at the same time as head of the physical education department and college physician. Both men have been connected with the Rochester faculty for twenty-eight and twenty-nine years respectively.

Civic Medal Goes to Dr. Kaiser.—On May 3 the Rochester Museum Association presented to Dr. Albert D. Kaiser, recently appointed health officer of Rochester, the Rochester Civic Medal. John Edward Hoffmeister, Ph.D., Rochester, president of the museum association, cited Dr. Kaiser for "civic responsiveness, his standing as a physician, his professional interest in public health and his achievements in the fields of exploration, scholarship and leadership."

County Society Opens New Headquarters.—The Richmond County Medical Society recently opened a permanent office in the Medical Arts Building, 100 Central Avenue, St. George, Staten Island 1. While the society does not plan to

engage a full time executive secretary, an information bureau will be maintained giving service concerning medical conferences in the hospitals, civilian and military, and miscellaneous data. Mrs. R. Hefftner will continue the secretarial services of the society, a position she has held for the last five years.

Physical Fitness Check-Up Week.—The week of June 4-8 has been designated physical fitness check-up week for high school pupils in New York State. The observance was held last year for the first time. The program this year will include medical and dental examinations, follow-up services, health instruction and practice, and achievement in physical activities based on statewide standards that were issued last September. These standards were developed in cooperation with the Selective Service System and the Army and Navy and represent achievements in individual developments that will mean better physical fitness for boys and girls in both wartime and postwar living.

Albert Fisher Honored.—Dr. Albert K. Fisher, Ossining, was honored with a dinner at the Cosmos Club, Washington, D. C., recently to celebrate his eighty-ninth birthday. Dr. Fisher, who graduated at Columbia University College of Physicians and Surgeons, in 1879, left the practice of medicine to enter the field of natural history. In 1883 he helped found the American Ornithologists' Union. On July 1, 1885, he became associated with the U. S. Department of Agriculture when a unit was set up there to study the interrelation of birds and agriculture. Dr. Fisher was associated with the unit for forty-six years, was a member of the Death Valley Expedition of 1891, of the Harriman (Alaska) Expedition of 1889 and the Pinchot South Sea Expedition of 1929 and from 1902 to 1906 assistant chief of the U. S. Biological Survey, later serving as senior biologist in charge of the division of economic investigations, under which the field organization of cooperative predatory animal and rodent control was built up. In 1931 he was retired from the department and was given an honorary appointment as collaborator in biology in the U. S. National Museum.

New York City

Grants to Columbia.—Columbia University recently announced $50,428 in gifts. The contributions for medical work include $15,000 from the Josiah Macy Jr. Foundation for research in the school of medicine and $8,000 from the Rockefeller Foundation for research in neuropathology.

Alumni Meeting.—The Alumni Association of the New York University College of Medicine is holding its ninth annual Alumni Day at the college, May 26. Dr. Donal Sheehan, acting dean, will review the college activities in the past year and discuss plans for the development of the new medical center, and Dr. George G. Deaver will discuss "Plans for the Development of the Baruch Division of Physical Medicine and Rehabilitation."

The Medical Quarterly.—The Alumni Association of the New York University College of Medicine has begun the regular publication of the *Medical Quarterly*. Dr. Arthur C. De Graff is editor and Dr. Hippolyte M. Wertheim is chairman of the publications committee. This is the first time the alumni association has attempted any such publication, the first issue of which appeared in April containing articles of general interest to the alumni regarding the school's history, its present activities and its plans for development, news items about the college and college organizations, and news and personals about individual alumni and members of the faculty.

Personal.—Dr. Nolan D. C. Lewis, medical director of the New York State Psychiatric Institute and Hospital, has been appointed editor of the *Journal of Nervous and Mental Disease* succeeding Dr. Smith Ely Jelliffe, Huletts Landing, who retired because of ill health.——Dr. John Mark Hiebert has been elected vice president of Sterling Drug, Inc., in charge of the Frederick Stearns and Company Division. Dr. Hiebert has been a member of the Sterling organization since 1934, advancing from the position of divisional vice president and general manager of the Stearns division, to which he was appointed when Stearns was acquired about a year ago (THE JOURNAL, June 17, 1944, p. 505).——Dr. Jacob Sobel has been appointed medical director of the Home and Hospital of the Daughters of Israel for the Aged.

Welfare Council Opens Conference Service.—On May 10 the Welfare Council of New York City announced the establishment on an experimental basis of a conference service for its 600 member agencies. The new service will be made available to the council's membership in eight broad functional groups: health services, family service and related case work services, child care, employment and vocational guidance, correctional and allied services, care of the aged, group work and recreation, and services for seamen. The purpose of the new service is "to facilitate the work of the council's standing committee on welfare and health services by establishing direct channels of communication between it and member agencies of the Welfare Council and by providing a means of exchanging information among agencies in functional groups." The conference service will operate experimentally for one year.

PENNSYLVANIA

Philadelphia

New Auditorium at Woman's Medical College.—On May 1 the Mary Dern Goodrich Auditorium was opened at the Woman's Medical College of Pennsylvania. The new section is named for the wife of Judge Herbert F. Goodrich, president of the college, who spoke at the official opening. The redecoration of the room and its equipment for motion picture and sound projection are the gifts of Mr. William Goldman. Dr. William G. Leaman Jr., professor of medicine at the medical college, showed the first and latest medical films taken at the college.

The Ulrich Memorial Lecture.—Dr. Roy E. Nicodemus, director of the department of obstetrics, George F. Geisinger Memorial Hospital, Danville, delivered the first George A. Ulrich Memorial Lecture, April 26, at Jefferson Medical College of Philadelphia. His subject was "The History of American Obstetrics." The lecture, which is named for Dr. George A. Ulrich, who died July 18, 1944, will be sponsored annually by the Epsilon charter of Alpha Kappa Kappa fraternity of Jefferson Medical College. Dr. Ulrich was clinical professor of obstetrics at Jefferson, where he graduated in 1901.

Program on Health Education.—On May 2 the Philadelphia Department of Public Health launched a concentrated year round educational campaign to improve the health of the citizens of Philadelphia. Attention is to be focused on pertinent facts concerning those diseases which constitute the greatest menace, and the medical schools, local professional groups and allied agencies are cooperating. A steering committee has been set up and the department of health will provide speakers and educational material, including sound motion picture films. The first program is devoted to tuberculosis and a slogan chosen to be used throughout the campaign is "*Is There Tuberculosis in Your Home? Find Out!*" Similar programs will be carried out for rheumatic heart disease, nutrition, child health, diabetes, cancer, venereal disease, labor, industry and industrial medicine, respiratory diseases, clubs, personal hygiene and mental hygiene.

RHODE ISLAND

Personal.—Dr. John F. Kenney, Pawtucket, has been installed as president of the New England Conference of Industrial Physicians, succeeding Dr. Daniel L. Lynch, Boston. Dr. Thomas P. Kendrick, Boston, is the president-elect.

Proposed Institute of Pathology.—The establishment of a central Institute of Pathology to serve many or all of the hospitals in Rhode Island has been proposed by the committee on university, hospital and medical society relations of the Rhode Island Medical Society. It is recommended that the staff of the institute be large enough so that each hospital can have the personal attention of experts for frozen sections, conferences, staff meetings, tumor clinics, teaching of interns and residents and perhaps some lecturing to student nurses. It was also recommended that the work of all technologists be supervised by experts in bacteriology and biochemistry, the hospital technologists to be kept up to date by periodic review and training at the central laboratories of the proposed institute. Under the proposed setup a system of residency in pathology in preparation for national board certification would be an important part of the organization. Men qualifying for this work would receive a part of their training, third or fourth year, as resident pathologists in the larger of the participating hospitals. The institute would have a board of directors representing participating hospitals and a medical advisory committee consisting of one representative from each participating hospital. According to the outline of the plan, two or more technologists would fill in at hospitals while their regular technologists were at the institute for additional training and during vacations. Surgical specimens could be collected each day and examined at the institute, and pathologists would go out from the institute to the hospitals for frozen sections and necropsies. All serologic tests would be done at the institute, as would less common and more com-

plicated chemical and bacteriologic procedures. The proposal suggests that costs be shared by participating hospitals on the basis of the number of beds or other arrangements made by the board of directors. Each hospital would continue to charge its own patients for laboratory work according to its own plan.

SOUTH CAROLINA

Personal.—Dr. Franklin L. Geiger, Columbia, assistant director of rural sanitation, state board of health, has been appointed medical director of a tuberculosis survey which is being carried on in South Carolina.——Walter L. Hard, Ph.D., assistant professor of histology, University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, has been appointed assistant professor of anatomy at the Medical College of the State of South Carolina, Charleston, *Science* reports.

New President of State Society.—At the executive meeting of the council of the South Carolina Medical Association in Columbia, April 17, Dr. William Thomas Brockman, Greenville, was installed as president. Dr. William R. Wallace, Chester, had asked to be relieved of his activities as president. The action of the council was over the protest of Dr. Brockman, who took the position, it is reported, that the constitution and by-laws provided that his installation should occur at the annual meeting of the association and that, if Dr. Wallace wished relief and resigned, the vice president should automatically assume the presidency.

PUERTO RICO

University News.—Dr. Leland E. Hinsie, professor of psychiatry of the Columbia University College of Physicians and Surgeons, New York, gave a series of lectures on psychosomatic medicine at the School of Tropical Medicine in San Juan recently. Dr. Hinsie also addressed the Ponce District Medical Society on "The Person in the Body," the student body of the Polytechnic Institute at San Germán on "What Is Psychiatry?" and the students of social work at the University of Puerto Rico on "Psychosomatics in Social Work."

Funds for New Construction.—The legislative assembly of Puerto Rico recently passed bills for the construction of a new district charity hospital in Caguas to cost $1,500,000. This hospital is included in a six year financial plan of the government. Other legislation was passed appropriating $500,000 for expansion of the Psychiatric Hospital of Puerto Rico, Rio Piedras, and $500,000 for the Cancer Institute. Similar legislation provides for new additions to the Municipal Hospital at Trujillo Alto and one in Anasco. Plans allow for the construction of municipal hospitals in Naranjito, Corozal and Rincon.

GENERAL

International Surgical Assembly.—The fifth International Assembly of the International College of Surgeons and tenth anniversary of its foundation in Geneva, Switzerland, will be celebrated at the invitation and under the auspices of the Peruvian government and the Peruvian chapter of the International College of Surgeons in Lima, Peru, September 10-12. Dr. Francisco Graña, head of the surgical department of the University of Lima, Peru, is general chairman. Additional details may be obtained from Dr. Max Thorek, general secretary of the college, 850 Irving Park Road, Chicago.

Pan American Congress of Otolaryngology.—The first Pan American Congress of Oto-Rhino-Laryngology and Broncho-Esophagology, to be sponsored by the American Academy of Ophthalmology and Otolaryngology, will take place October 12-13 at the Palmer House, Chicago, immediately following the 50th anniversary meeting of the academy. If transportation conditions permit, a representative attendance is expected from all of the Latin American countries. The academy committee has been in touch with the officers of the various Latin American otolaryngologic societies and through them has received assurance of fullest cooperation in this congress. Dr. Chevalier L. Jackson, Philadelphia, is chairman of the committee on Pan American Congress of Otolaryngology of the academy.

Report of International Health Division.—Chief activities of the health commission of the International Health Division of the Rockefeller Foundation in 1944 were louse control studies in Mexico, typhus and malarial control in Italy, malarial work in Egypt, the study of infective jaundice and other infectious diseases, nutrition studies in England and the manufacture and distribution of yellow fever vaccine. These projects were financed by $1,000,000 earmarked for this emergency work out of the total budget of $3,200,000 for the entire division. In 1944 attention was concentrated on twelve specific diseases, the most important of which were yellow fever, malaria, typhus, and the deficiencies related to nutrition. Perhaps the most significant contribution of the International Health Division to public health has been in the field of public health education. In 1944 fairly substantial sums were appropriated for fellowships and travel grants and for the support of schools of hygiene and public health nursing and to support nursing schools in Canada, Colombia, Brazil, Ecuador, Argentina, Venezuela and Portugal. According to the annual report, the division carried on operations in twenty-three different countries. In its research program the report of the division indicates that significant was the discovery of active virus of yellow fever in a sick monkey, a marmoset. The animal was seriously ill and soon died after it had been trapped in June 1944 by the laboratory at Ilhéus, Brazil. Exhaustive laboratory tests showed conclusively that it had died of yellow fever. The episode is historically interesting, the report points out, because it is the first time in any country that a wild animal has been picked up in its natural habitat suffering from yellow fever and holds support to the thesis that yellow fever is primarily a disease of jungle animals transmitted by "jungle mosquitoes."

Services in Alcohol Hygiene.—The National Committee on Alcohol Hygiene, Inc., Baltimore, announces the availability of a bimonthly publication, *Alcohol Hygiene*, to be used for educational purposes. The committee also announces the following services:

Scientific medical worker speakers for lay and other seriously minded students of alcoholism
A research staff to organize and sponsor institutes
A clearing center for proper evaluation of published material by the scientific research committee and for distribution of acceptable reprints
Consultation service for Community Chest and other groups to aid in the organization of medically and psychiatrically supervised alcoholic diagnostic and treatment clinics.
Material on fundamental preventive measures based on practical medical psychiatric knowledge and experience, and on treatment of the individual who has an alcohol problem.

Dr. Robert V. Seliger, Baltimore, is executive director of the National Committee on Alcohol Hygiene and Robert M. Lindner, Ph.D., Lewisburg, Pa., director of educational and editorial projects. Dr. Lawrence F. Woolley, Baltimore, is director of clinical investigators, and Victoria Cranford is director of scientific investigators.

CANADA

The Jackson Memorial Lecture.—Dr. Stanley Cobb, Bullard professor of neuropathology, Harvard Medical School, Boston, delivered the tenth annual Hughlings Jackson Memorial Lecture of the Montreal Neurological Institute, May 9, on "Some Observations on Neurocirculatory Asthenia." Following the address, a specially bound volume of the "Selected Writings of John Hughlings Jackson," edited by James Taylor, was presented to the lecturer.

Changes in Health Personnel.—John T. Phair, D.P.H., Toronto, chief medical officer of the Ontario Department of Health, has been appointed deputy minister of health to succeed the late Dr. Bernard T. McGhie. Dr. Aquila Lapierre, Outremont, Quebec, has been appointed director general of the administrative and technical services of the ministry of health and social welfare of the province of Quebec. He held the position from 1936 to 1939.

Canadian Medical Meeting.—The seventy-sixth annual session of the Canadian Medical Association will be held at the Mount Royal Hotel, Montreal, June 11-15, under the presidency of Dr. John Harris McPhedran, Toronto. The preliminary program includes the following speakers:

Dr. Gabriel Nadeau, Rutland, Mass., Obstetrics and Gynecology in New France.
Dr. Albert D. Ruedemann, Cleveland, Use of Beta Radium in Lesions of the Eye.
Dr. Alexander E. MacDonald, Toronto, New Treatment of Entropion
Dr. Owen H. Wangensteen, Minneapolis, The Management of Bowel Obstruction
Dr. Reginald P. Vivian, Port Hope, Ont., minister of health for Ontario, Role of Public Health in the Practice of Medicine.
Surg.-Lieut. Comdr. Donald S. Mitchell, Experiences of Penicillin in Dermatitis in the Forces.
Dr. Frederick A. Willius, Rochester, Minn., Critical Evaluation of Methods of Diagnosis in Cardiac Disease, with Special Reference to Electrocardiography.

Other groups meeting simultaneously will include the Canadian Orthopaedic Association, Canadian Association of Radiologists, Canadian Society for the Study of Diseases of Children, Federation of Medical Women of Canada, Canadian Medical Protective Association, Canadian Society for the Control of Cancer and Royal College of Physicians and Surgeons of Canada.

Foreign Letters

LONDON

(From Our Regular Correspondent)

April 21, 1945.

The Physiologic Problem of Tickle Due to Wool Next the Skin

The director of research to the Wool Industries Association, Mr. B. H. Wilsdon, states in his annual report that a physiologic problem arises in the use of wool next the skin—that of tickle. This he describes as an *idiosyncrasy* for which no adequate explanation has been given. There is evidence that the reaction can be moderated when wool is given chemical treatment, such as that afforded by papain, which reduces the scaliness of the fiber. But he avoided claiming that this treatment produces "nontickle fiber." He believed that certain sensitive subjects may still react. The type of reaction may be quite dissimilar in different cases. The possibility must not be disregarded that some degree of tickle may be of hygienic value in stimulating the skin and controlling the peripheral circulation.

Consultants and the Proposed National Health Service

Two meetings of London consultants—one for those attached to hospitals south of the Thames and the other for those attached to hospitals north of the Thames—were called by the British Medical Association and the Royal Colleges to discuss the government's proposals for a national health service. Lord Moran, president of the Royal College of Physicians, who presided at the former meeting, urged that any central health services council should have real powers and not be a reproduction of many old advisory bodies with purely negative functions. Even more important was it that power should be given to the regional councils—expert bodies which would have to deal with local authorities. A committee of ninety-three representative of the Royal Colleges, the British Medical Association, the teaching hospitals and the universities had unanimously urged that these *councils should be planning bodies*, with advisory powers over finance. The crux of the whole problem was the medical profession's fear of interference by local authorities in clinical work. If the regions were based on university centers and the planning was done from these in such a manner as to afford consultants a voice, they would not be at the mercy of local bodies. As far as negotiations with the government had proceeded, any substantial concessions gained had been in the field of general practice, not in that of consultant or specialist practice.

Sir Alfred Webb-Johnson, president of the Royal College of Surgeons, who presided at the other meeting, concurred in Lord Moran's view as to the need for investing the regional councils with real powers. Among matters which he hoped would still be pressed on the government were the separation of the medical service from the general social insurance, the introduction of the service by stages (the development of the hospital system coming first) and the bringing together of all health services under the Ministry of Health. In closing the meeting he said that he thought we were getting near to an administrative structure which would be acceptable to the profession.

Sir Thomas Lewis

The death of Sir Thomas Lewis at the age of 64 has removed from British medicine a great investigator of disease. The method which he made his own and never tired of advocating he termed "clinical science," the main innovation being to bring the methods of the laboratory to the bedside. He condemned the usual separation of clinical and laboratory work into the hands of different persons. The clinician should perform both. He regarded the chief weapon of medicine to be the experimental method directly applied to man. His most important work was done on diseases of the heart. He was turned in this direction by the influence of Mackenzie, the leading cardiologist of the day, a position to which Lewis succeeded. Mackenzie was deeply interested in the mechanism of persistent cardiac irregularity, which his polygraphic studies led him to attribute to "nodal rhythm"; but the introduction of Einthoven's string galvanometer enabled Lewis (simultaneously with two Austrian workers) to show that the cause was auricular fibrillation. The discovery of auricular flutter followed. Experience in the war of 1914-1918 led to investigation of soldier's heart, which he embodied in the book "The Soldier's Heart and the Effort Syndrome." Other works, all of which became standard, were "Mechanism and Graphic Registration of the Heart Beat," "Clinical Disorders of the Heart Beat" and "The Blood Vessels of the Human Skin and Their Responses." He investigated dermatographia and produced evidence for the independent contractility of the capillaries. He described "a triple response" of the tissues of the skin to injury, due to release from the injured cells of a histamine-like substance. Experimental and clinical studies were embodied in a remarkable book entitled "Pain," in which he showed that pain arising from the skin was of a different kind from pain arising deeply. He showed the intervention of chemical agents in the production of cutaneous pain and tenderness. He attributed the latter to axon reflexes through fibers not previously known, which he termed "nocifensor." He also showed the segmental distribution of pain arising from deep structures. His work received early recognition in the United States. In 1914, at the early age of 33, he delivered the Herter lectures at Baltimore and a Harvey lecture in New York. For a period he was visiting physician attached to the Peter Bent Brigham Hospital, Boston. All his advances were made by the experimental investigation of disease in man, which he was always strenuously advocating. He was editor of two journals devoted to research: *Heart* from its foundation in 1908 and its successor *Clinical Science* until last year.

German Ill Treatment of British Prisoners of War

Plans are completed for the reception in this country of 160,000 liberated British prisoners of war. Camps are being prepared for them at coastal resorts with staffs of doctors, specialists and welfare officers. Many men will require building up after the malnutrition and ill treatment endured in German prison camps. Every man will receive the usual forty-two days' leave and double rations. A report from Hanover describes 100 prisoners too ill to move. Among them were 32 who had survived a grueling march of 500 miles across Germany to prevent their liberation by the approaching Allied army.

Marriages

FRANCIS LEO DENZER, Brooklyn, to Miss Marie Loretta Mooney at Flushing, N. Y., May 8.

WILLIAM CLARKE QUINN, Crisfield, Md., to Miss Jean Quinn of Statesville, N. C., March 31.

JOHN B. BLALOCK to Miss Margaret Ashe Tutwiler, both of Birmingham, Ala., April 14.

EDWARD M. POSER, Columbus, Wis., to Miss Elizabeth Ann Shearer of Edgerton recently.

HAL E. BENNETT, Troy, Tenn., to Miss Joan Ottilee Tabor of Belvidere, Ill., April 11.

LAWRENCE V. LITTIG, Madison, Wis., to Miss Sally Margaret Ebert, Cuba City, recently.

WILLIAM BROWN to Dr. Elizabeth L. Brown, both of New York, April 12.

HARRY A. SHEARER to Miss Violet Lundt, both of Beloit, Wis., recently.

Deaths

Walter Gray Crump Sr., ⊕ New York; New York Homeopathic Medical College and Hospital, New York, 1895; emeritus professor of surgery at his alma mater, now known as the New York Medical College, Flower and Fifth Avenue Hospitals; served as professor of surgery at the New York Polyclinic Medical School and Hospital and as professor of gynecology at the New York Medical College and Hospital for Women; member of the Academy of Pathological Science; member of the board of governors and fellow of the American College of Surgeons; director of the National Association for the Advancement of Colored People; a founder of the Broad Street Hospital, where he had been medical director and attending surgeon; a founder of the Beekman Street Hospital; consulting surgeon, Evangelical Deaconess and Prospect Heights hospitals, Brooklyn, Yonkers (N. Y.) General Hospital, Southside Hospital, Bay Shore, N. Y., Mount Vernon (N. Y.) Hospital, Dobbs Ferry (N. Y.) Hospital, Fitkin Memorial Hospital, Neptune, N. J., and the Flower and Fifth Avenue Hospitals; consulting gynecologist at the United Hospital in Port Chester, N. Y.; trustee, Howard University in Washington, D. C., and the Tuskegee Institute in Alabama; in 1934 received the honorary degree of doctor of science from the Albright College in Reading, Pa.; died in the Flower and Fifth Avenue Hospitals May 1, aged 75.

Charles Morgan McKenna ⊕ Chicago; Rush Medical College, Chicago, 1905; professor and head of the division of urology in the department of surgery at the University of Illinois College of Medicine which he had joined in 1913 as instructor in senior surgery; specialist certified by the American Board of Urology, Inc.; member of the American Association of Genito-Urinary Surgeons and the Institute of Medicine of Chicago; member and in 1922-1923 president of the Chicago Urological Society; member of the American Urological Association and past president of the North Central Branch; fellow of the American College of Surgeons; a captain in the medical corps of the U. S. Army during World War I; head of genitourinary surgery at the Research and Educational Hospitals and St. Joseph Hospital; attending urologist at the Norwegian-American Hospital; attending urologist at the Cook County Hospital from 1927 to 1938; contributed a chapter on "Tuberculosis of the Urogenital Tract" in Clinical Tuberculosis by Dr. Benjamin Goldberg; died May 13, aged 65, of coronary occlusion.

Henry W. Grady Shytles, Abilene, Texas; University of Tennessee College of Medicine, Memphis, 1914; president of the Taylor County Medical Society in 1930 and of the Scurry-Dickens-Kent-Garza-Borden-King-Stonewall Counties Medical Society from 1939 to 1943; member of the American Medical Association; during World War I associated with the U. S. Public Health Service, inspecting army camps throughout the country; for three years physician and surgeon for the Pima Indian reservation in Arizona; while residing at Snyder, Texas, served as chairman of the Procurement and Assignment Advisory Committee for that area; formerly medical superintendent and chief surgeon of the Snyder (Texas) General Hospital; at one time assistant city physician in Fort Worth; a captain in the medical corps, Army of the United States, from April 1943 to August 1943, when he was honorably discharged because of his physical condition; on the staffs of St. Ann and the Hendrick Memorial hospitals; died Nov. 16, 1944, aged 53, of coronary thrombosis.

James Thomas Wayson ⊕ Honolulu, Hawaii; University of California Medical School, San Francisco, 1891; surgeon in the U. S. Cutter Service from 1892 to 1895; member of the House of Delegates of the American Medical Association in 1905; served as assistant administrator and member of the board of health of Hawaii; city and county physician of Honolulu from 1911 to 1918 and general health officer of Hawaii from 1918 to 1931; in 1932 was instrumental in setting up a separate board of hospitals and settlement to administer the leprosy phase of public health; held the position of board physician from the time of its inception until his retirement in 1943; served as chairman of the Hawaii Territorial Medical Examiners; member of the American Academy of Dermatology and Syphilology; at one time physician in charge of the Kalihi Boys' Home and superintendent of the Kapiolani Girls' Home; died January 11, aged 74.

Archibald Henry Busby, New Canaan, Conn.; Columbia University College of Physicians and Surgeons, New York, 1898; decorated for gallantry in the Battle of San Juan Hill during the Spanish-American War; served in France with the New York Hospital Unit, Base Hospital number nine during World War I; fellow of the New York Academy of Medicine; charter member of the New York Roentgen Society; for many years head of the radiology department of the New York Hospital in New York, where since 1932 he had been consulting radiologist; at various times on the staffs of the Babies Hospital, French Hospital and St. Mary's Hospital for Children, all in New York; died April 25, aged 69, of heart disease.

James Herbert Lawson, New York; Columbia University College of Physicians and Surgeons, New York, 1902; one of the early officers of the medical reserve corps of the army, receiving his commission from President Taft in 1912; was with the American troops on the Mexican border in 1916; received a decoration from the French government for service during World War I; served at St. Vincent's and Lying-In hospitals; formerly attending surgeon at the Memorial Hospital and had been chief surgeon of the outpatient department at the Babies Hospital and of St. Mary's Hospital for Children; surgeon for many American Olympic teams; died April 25, aged 69, of coronary arteriosclerosis.

Edmond Henri Sauvignet ⊕ Laredo, Texas; Medical Department of Tulane University of Louisiana, New Orleans, 1898; formerly secretary and president of the Webb-Zapata-Jim Hogg Counties Medical Society; served as health officer of Webb County and of the city of Laredo; a charter member of the International Congress on Tuberculosis; examining physician for Webb County Draft Board during World Wars I and II; first resident physician and surgeon at the Santa Rosa Hospital in San Antonio from 1898 to 1900; on the staff of Mercy Hospital; district surgeon for the Missouri Pacific Railroad from 1901 to 1945; died January 27, aged 70, of uremia.

Rebekah Wright, Brookline, Mass.; Northwestern University Woman's Medical College, Chicago, 1896; member of the American Medical Association, American Psychiatric Association and the New England Society of Psychiatry; for many years associated with the Massachusetts State Department for Mental Diseases as a consultant in hydrology for all of the state's hospitals for mental and nervous diseases; since February 1, 1945 consulting hydrologist at the Connecticut State Hospital in Middletown, Conn., where she died March 29, aged 72, of arteriosclerotic myocarditis.

Charles Berger Campbell ⊕ Washington, D. C.; Georgetown University School of Medicine, Washington, 1894; also a pharmacist; major, medical corps, U. S. Army, not on active duty; served as chairman of the public health committee of the Federation of Citizens Associations of the District of Columbia and its delegate from the Medical Society of the District of Columbia; in 1944 was awarded the Evening Star Trophy for outstanding civic work; died in the Emergency Hospital February 5, aged 74, of uremia, hypertrophy of the prostate and pneumonia.

John George Abele, Portland, Ore.; University of Oregon Medical School, Portland, 1907; formerly city epidemiologist and city health officer; served during World War I; died in the Veterans Administration Facility, Roseburg, March 14, aged 74.

Homer C. Ballard, Lakewood, Ohio; Western Reserve University Medical Department, Cleveland, 1896; formerly on the staffs of the Lutheran and St. John's Hospital in Cleveland; on the staff of the Lakewood Hospital, where he died March 27, aged 77.

George Louis Bartruff, Brooklyn; Long Island College Hospital, Brooklyn, 1893; died March 10, aged 77.

Ira Floyd Bean, Melbourne, Fla.; Atlanta College of Physicians and Surgeons, 1912; member of the American Medical Association; died in a hospital at Jacksonville February 18, aged 59.

Theophilus Henry Boysen ⊕ Egg Harbor City, N. J.; Jefferson Medical College of Philadelphia, 1905; also a pharmacist; past president of the Medical Society of Atlantic County; served as medical examiner in the public schools, as a member of the board of health and at one time as councilman; died in the Jefferson Hospital, Philadelphia, March 30, aged 63.

Benjamin Harrison Breakstone, Chicago; Rush Medical College, Chicago, 1899; member of the American Medical Association; formerly professor of surgery at the Bennett Medical College; attending surgeon at the Cook County Hospital from 1902 to 1908; served on the staffs of the Mary Thompson Hospital for Women and Children, the People's Hospital and various other hospitals in Chicago; died April 23, aged 68.

William Lewis Colquhoun MacBeth, El Monte, Calif.; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1909; member of the American Medical Association; died March 1, aged 58.

William Henry Dale, Eugene, Ore.; Rush Medical College, Chicago, 1904; member of the American Medical Association; past president of the Central Willamette Medical Society; served as a member of the board of health; at one time medical superintendent of the Harrisburg Private Hospital in Harrisburg; died March 14, aged 66.

James Francis Dennis ⊕ Waterloo, Wis.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1908; died March 29, aged 62, of carcinoma of the sigmoid.

Albert Powell Donoho, Merchantville, N. J.; Medico-Chirurgical College of Philadelphia, 1900; served during World War I; died in the Temple University Hospital, Philadelphia, February 16, aged 69.

Louis Warner Flanders ⊕ Dover, N. H.; University of Vermont College of Medicine, Burlington, 1885; past president of the New Hampshire Medical Society; honorary member of the Strafford County Medical Society; died January 16, aged 80.

Edward Richard Gookin ⊕ Washington, D. C.; Baltimore Medical College, 1906; served overseas during World War I; formerly clinical instructor in ophthalmology at the George Washington University School of Medicine and assistant and later instructor in clinical ophthalmology at the Georgetown University School of Medicine; died March 6, aged 62, of coronary occlusion.

Daniel Wesley Gray, Searcy, Ark.; Memphis (Tenn.) Hospital Medical College, 1908; died suddenly February 5, aged 65.

Forest Jackson Green, Mineola, Texas; Dallas Medical College, 1903; member of the American Medical Association; examining physician and member of a draft board during World War I; died January 11, aged 66, of coronary occlusion.

Thaxton Richardson Guill ⊕ Donelson, Tenn.; University of Nashville Medical Department, 1900; served as director of the Bank of Donelson; died March 22, aged 67, of heart disease.

William Dandridge Haden ⊕ Charlottesville, Va.; University of Virginia Department of Medicine, Charlottesville, 1910; served three terms as mayor and twelve consecutive years as a member of the city council; member of the board of visitors of the University of Virginia; president of the National Bank and Trust Company; died in the University Hospital April 8, aged 60.

James Thomson Hardy ⊕ Brooklyn; New York Homeopathic Medical College and Hospital, New York, 1900; veteran of the Spanish-American War; on the staffs of the Bushwick, Lutheran and Wade hospitals; died in the Nassau Hospital, Mineola, March 10, aged 68, of arteriosclerotic heart disease, auricular fibrillation and hypertrophy of the prostate.

Richard Henry Harris, Elkins Park, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1898; member of the American Medical Association; on the staff of the Abington Memorial Hospital, Abington, where he died March 29, aged 75, of cardiac insufficiency and cerebral thrombosis.

Victor Hugo Hasek, Cedar Rapids, Iowa; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1916; member of the American Medical Association; city physician and health officer; served during World War I; on the staffs of the Mercy and St. Luke's hospitals; died February 25, aged 53, of cerebral embolism of the left middle cerebral artery.

Walton Hewetson, Groveport, Ohio; Columbus Medical College, 1888; died February 18, aged 78.

Edwin Carlton Higgins, Manchester, Conn.; Tufts College Medical School, Boston, 1925; member of the American Medical Association; interned at St. Francis and Hartford Isolation hospitals in Hartford; on the staff of the Manchester Memorial Hospital; died March 31, aged 47, of coronary occlusion.

Bayard Holmes, Chicago; Rush Medical College, Chicago, 1904; on the consulting staff of the Illinois Masonic Hospital; on the courtesy staffs of St. Luke's and Henrotin hospitals; life member of the Art Institute of Chicago; died March 13, aged 65, of congestive heart disease and angina pectoris.

John Howorth ⊕ Wilkes-Barre, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1909; fellow of the American College of Surgeons; past president of the Luzerne County Medical Society; served on the medical advisory board during World Wars I and II as well as on the surgical staff of the local induction center during the present war; chief of staff, Wilkes-Barre General Hospital; surgeon for the Lehigh Valley Railroad; died March 24, aged 65, of myocarditis.

Marion Mercer Hursh, Grand Rapids, Minn.; Minneapolis College of Physicians and Surgeons, medical department of Hamline University, 1908; served on the staff of the Itasca County Hospital; died January 20, aged 67.

Harvey Green Johnston, Pearisburg, Va.; University College of Medicine, Richmond, 1899; served as county medical examiner for the Selective Service during World Wars I and II; died March 21, aged 66.

Moses Randolph Kahn, Baltimore; University of Maryland School of Medicine, Baltimore, 1912; member of the American Medical Association; clinical professor of ophthalmology at his alma mater; formerly instructor of clinical ophthalmology at the Johns Hopkins University School of Medicine; served during World War I; at various times on the staffs of the Baltimore Eye, Ear and Throat Charity Hospital, Home for Incurables, Sinai Hospital and the U. S. Veterans Bureau; died January 11, aged 57.

James William Kautz, Cincinnati; Cincinnati College of Medicine and Surgery, 1890; died March 8, aged 80, of lobar pneumonia and grip.

Theodore Wilbert Kemmerer, Jackson, Miss.; State University of Iowa College of Medicine, Iowa City, 1901; for many years director of the state hygienic laboratory; at one time adjunct professor of clinical laboratory diagnosis at the University of Mississippi School of Medicine; formerly associated with the hygienic laboratory of the U. S. Public Health Service in Washington, D. C.; veteran of the Spanish-American War and World War I; died April 5, aged 67, of edema of the lungs and auricular fibrillation.

Albert Koehler, Baker, Ore.; Schlesische-Friedrich-Wilhelms-Universität Medizinische Fakultät, Breslau, Prussia, Germany, 1877; member of the American Medical Association; died March 1, aged 98.

Werner Adolph Reinhold Lagus, Warrenton, Ore.; Helsingfors Universitet Medicinska Fakulteten, Helsingfors, Finland, 1896; died in a hospital at Astoria March 19, aged 79, of coronary occlusion.

Francis James Lawler ⊕ Carthage, N. Y.; Albany Medical College, Albany, 1916; health officer; served overseas during World War I; died in the Syracuse Memorial Hospital, Syracuse, March 23, aged 53, of myelogenous leukemia.

Oscar Leslie Long, Portland, Maine; Baltimore Medical College, 1898; for many years member of the city health department in Baltimore; died March 9, aged 71, of pulmonary edema, cerebral hemorrhage and arteriosclerosis.

William F. MacLennan, Gloucester City, N. J.; Medico-Chirurgical College of Philadelphia, 1896; also a pharmacist; died in Trenton March 24, aged 76.

Clib B. May, Little Rock, Ark.; University of Louisville Medical Department, Louisville, Ky., 1914; member of the American Medical Association; died February 23, aged 64.

Luster Clark McCutcheon, Green Bank, W. Va.; Chattanooga (Tenn.) Medical College, 1910; served a term as mayor of Richwood; died April 26, aged 61.

Robert Davis McKinney, Troy, N. Y.; Chicago Homeopathic Medical College, 1894; died January 3, aged 75, of carcinoma of the head of the pancreas.

Allan McLean, Morganton, N. C.; University of Maryland School of Medicine, Baltimore, 1908; member of the American Medical Association; for many years on the staff of the State Hospital; died February 22, aged 60.

Jason E. Montgomery, Weslaco, Texas; Baylor University College of Medicine, Dallas, 1908; member of the American Medical Association; local surgeon for the Missouri Pacific Railway; died suddenly January 30, aged 73.

Carl G. Muehlmann, Pekin, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900; also a pharmacist; for twenty years a surgeon for the Illinois Central Railroad; surgeon for the Pekin Terminal Railroad; for many years served on the U. S. Pension Board; until the time of his death examining physician for U. S. Civil Service applicants; health officer of Pekin; died in the Pekin Public Hospital March 13, aged 80.

Arthur Lapham Murray, Washington, D. C.; George Washington University School of Medicine, Washington, D. C., 1904; served during World War I; for many years medical adviser in the Bureau of Mines, Department of the Interior; died February 28, aged 63.

James Ball Naylor, Malta, Ohio; Starling Medical College, Columbus, 1886; at one time health commissioner of Morgan County; author of many books; died April 1, aged 84, of heart disease.

Herman J. Neubauer ⊕ Hinckley, Ill.; Chicago College of Medicine and Surgery, 1917; on the staffs of the DeKalb Public Hospital and St. Mary's Hospital in DeKalb, where he died March 23, aged 51, of fractured ribs received when he accidentally fell beneath the wheels of a farm machine on his farm.

William Peter Rice, Rhinelander, Wis.; Chicago College of Medicine and Surgery, 1915; died February 6, aged 63, of coronary occlusion.

Charles Orean Rickenbrode ⊕ Farrell, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1908; died February 10, aged 60.

Ivan Webster Riggins, Indianapolis; Kentucky University Medical Department, Louisville, 1906; University of Louisville Medical Department, 1907; medical examiner for the Indianapolis Life Insurance Company and Acacia Mutual Life Insurance Company; on the staffs of the City Hospital, St. Vincent's Hospital and the Methodist Hospital, where he died March 15, aged 71, of coronary occlusion.

William Ernest Risque, *Midway, Ky.; University of* Louisville Medical Department, Louisville, 1893; past president of the Midland Medical Society; died March 9, aged 85, of coronary sclerosis.

William Penn Roberts, Sioux Falls, S. D.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1894; honorary member of the South Dakota State Medical Association; member of the American Medical Association, died January 12, aged 75.

Thomas Peter Rothnem, Fargo, N. D.; *University of* Minnesota College of Medicine and Surgery, Minneapolis, 1912; specialist certified by the American Board of Radiology, Inc.; member of the Radiological Society of North America, Inc.; on the staffs of St. Luke's Hospital and Fargo Clinic; died January 19, aged 61.

Daniel Ralph Russell, Kansas City, Mo.; University Medical College of Kansas City, 1908; member of the American Medical Association; died March 22, aged 64.

Ord Ledyard Sands, Binghamton, N. Y.; *University and* Bellevue Hospital Medical College, New York, 1911; member of the American Medical Association; died January 23, aged 73, of coronary occlusion.

Eugene Schumaker, Rensselaer, Ind.; Rush Medical College, Chicago, 1934; interned at St. Joseph Hospital in Chicago; on the staff of the Jasper County Hospital; died March 12, aged 38, of coronary occlusion.

Charles Young Seagle ⊕ Bertrandville, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1904; died January 29, aged 67.

Sam L. Segraves, Era, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1889; died February 21, aged 91, of general senility.

Ebert T. Simpson, Butler, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1908; member of the American Medical Association; died January 2, aged 63, of coronary embolism.

Clyde Leroy Smith ⊕ Fremont, Ohio; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1904; past president of the Sandusky County Medical Society; since 1940 city health commissioner and registrar; on the staff of the Memorial Hospital; died February 28, aged 66, of coronary occlusion.

Dorland Smith ⊕ Bridgeport, Conn.; Yale University Medical School, New Haven, 1899; specialist certified by the American Board of Ophthalmology and the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology, American Ophthalmological Society and the Association for Research in Ophthalmology, Inc.; fellow of the American College of Surgeons; on the staff of the Bridgeport Hospital; died February 5, aged 69, of carcinoma of the pancreas with metastases to the liver.

William Curtis Smith, Scottsville, N. Y.; University of the City of New York Medical Department, New York, 1881; member of the American Medical Association; for many years St. Lawrence County coroner and supervisor of the town of Stockholm, where he was also health officer; served as director of the First National Bank of Winthrop from its inception in 1916 until his resignation in 1942; died March 2, aged 87, of lobar pneumonia.

Fred Clifford Soper, Dilworth, Minn.; State University of Iowa College of Medicine, Iowa City, 1905; coroner of Clay County; on the staff of the St. Ansgar Hospital in Moorhead; died in St. John's Hospital, Fargo, N. D., February 7, aged 63, of pneumonia.

Albert A. Sprague, Silverton, Ohio; Medical College of Ohio, Cincinnati, 1898; for many years secretary of the Silverton Building and Loan Company; died February 19, aged 82.

Neile Spooner Storer ⊕ Republic, Ohio; Northwestern University Medical School, Chicago, 1906; served as mayor of Republic; on the staff of the Mercy Hospital in Tiffin; died February 28, aged 61, of coronary thrombosis.

Ernest Bernard Studer, Los Angeles; St. Louis Medical College, 1890; University of Pennsylvania Department of Medicine, Philadelphia, 1891; served on the staff of St. Vincent's Hospital; died March 19, aged 78, of cerebral hemorrhage.

Gustave Herman Taubles ⊕ Carmel, Calif.; Cooper Medical College, San Francisco, 1908; served as chairman of the Carmel chapter of the American Red Cross; died January 24, aged 64.

John Allen Thomson, Sioux City, Iowa; Sioux City College of Medicine, 1904; member of the American Medical Association; formerly a member of the county board of health; member of the Selective Service Board number 2; died February 28, aged 65, of cerebral hemorrhage.

Clarence Scott Trimble ⊕ Emporia, Kan.; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1902; member of the American Academy of Ophthalmology and Otolaryngology and the Kansas City Eye, Ear, Nose and Throat Society; served during World War I; at one time health officer of Buckeye, Iowa; on the staffs of the Newman Memorial and St. Mary's hospitals; ophthalmologist for the Santa Fe Railroad for twenty-two years; died March 16, aged 67, of carcinoma of the stomach.

Joseph C. Tufford, San Diego, Calif.; Detroit College of Medicine, 1894; died February 16, aged 77, of uremia.

Urania Tyrrel, Philadelphia; New York Medical College and Hospital for Women, New York, 1890; died in the Hahnemann Hospital January 29, aged 77, of arteriosclerosis and coronary artery insufficiency.

Thomas Mervelle Watson ⊕ Greenville, N. C.; Tulane University of Louisiana School of Medicine, New Orleans, 1919; specialist certified by the American Board of Pediatrics, Inc.; member of the American Academy of Pediatrics; formerly vice president of the North Carolina Pediatric Society; served during World War I; interned at St. Vincent's Hospital in Birmingham, Ala., and St. Louis Children's Hospital in St. Louis; on the staff of the Pitt General Hospital; died March 12, aged 50, of coronary thrombosis.

Morris Weissberg ⊕ Brooklyn; Long Island College Hospital, Brooklyn, 1914; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; served in France during World War I; consulting physician at St. Luke's Hospital in Newburgh and at the Bushwick and Evangelical Deaconess hospitals; died March 17, aged 58, of coronary occlusion.

John Westall, Fall River, Mass.; Dartmouth Medical School, Hanover, N. H., 1892; served as president of the board of aldermen and a member of the board of health; died in the Truesdale Hospital, March 15, aged 83, of pyelonephritis and hypertrophy of the prostate.

Furman Chairs Whitaker, Bradenton, Fla.; the Hahnemann Medical College and Hospital, Chicago, 1895; died in the Tampa Municipal Hospital, Tampa, March 8, aged 88, of injuries received in a fall.

Reuben H. Wood, Stockton, Ill.; the Hahnemann Medical College and Hospital, Chicago, 1896; on the staffs of the Deaconess and St. Francis hospital in Freeport; died March 2, aged 85, of angina pectoris.

Henry Wilson Wooden, Orlando, Fla.; University of West Tennessee College of Medicine and Surgery, Memphis, 1914; Meharry Medical College, Nashville, 1916; died February 12, aged 53, of injuries received in an automobile accident.

Sarah Delia Wyckoff ⊕ Kingston, Pa.; Johns Hopkins University School of Medicine, Baltimore, 1899; died in the Wilkes-Barre General Hospital, Wilkes-Barre, Pa., March 19, aged 72, of acute cardiac failure and ruptured appendix.

George W. Young, Pennington Gap, Va.; Hospital College of Medicine, Louisville, Ky., 1898; died March 2, aged 70, of hypertensive heart disease.

DIED WHILE IN MILITARY SERVICE

Arthur Eynon Beddoe ⊕ Surgeon, Lieutenant Commander, U. S. Navy, retired, San Diego, Calif.; University of Pennsylvania Department of Medicine, Philadelphia, 1910; entered the medical corps of the U. S. Navy as a lieutenant (jg) on May 21, 1914; retired on May 1, 1937 for incapacity resulting from an incident of the service; returned to active duty; promoted to the temporary rank of commander on Jan. 3, 1942; died July 18, 1944, aged 59.

James Russell Bell ⊕ Canonsburg, Pa.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1932; interned at the Mercy Hospital in Pittsburgh; began active duty as a captain in the medical corps, Army of the United States, on June 5, 1942; later promoted to major; died near Prestwick, Scotland, in an aircraft crash in routine flight, Dec. 10, 1944, aged 40.

John Birge Byers, Grand Rapids, Mich.; Northwestern University Medical School, Chicago, 1941; interned at St. Luke's Hospital in Chicago; formerly a fellow in medicine in the Mayo Foundation, Rochester, Minn.; began active duty as a first lieutenant in the medical corps, Army of the United States, on June 6, 1942; later promoted to captain; a flight surgeon attached to an aircraft group in England, where he died Dec. 20, 1944, aged 32, of acute hemorrhagic pancreatitis.

Richmond Cranston Holcomb ⊕ Medical Director, Captain, U. S. Navy, retired, Upper Darby, Pa.; Long Island College Hospital, Brooklyn, 1896; entered the navy in December 1898 with the rank of lieutenant (jg); while in Culebra, Virgin Islands, carried on special investigations in connection with intestinal parasites, especially schistosomiasis; the fluke was shown to be a distinct species, leading Sambon to naming it Schistosomum mansoni; assistant to the Bureau of Medicine and Surgery, Navy Department, Washington, D. C., from April 1914, until April 1918; was medical officer in command of the U. S. Naval Hospital, League Island, Philadelphia, was the representative of the Bureau of Medicine and Surgery in connection with the building of the U. S. S. *Relief*, the first hospital ship, which he served as its first commanding officer; was in command of the Naval Hospital, Norfolk, Va., from August 1926 to June 1930, with additional duty as medical officer in command, Pharmacist's Mates School, Naval Hospital, Norfolk; district medical officer in the Fourth Naval District, and from January until December 1931 commanded the Naval Hospital, League Island, Philadelphia; retired in December 1932; before being recalled to the service in 1943, was state medical director for Delaware and Chester counties, Pennsylvania; besides the Navy Cross, awarded him in World War I, received numerous honors for his activities in the Spanish-American War, the Boxer Rebellion and the Philippine campaign; an authority and liberal writer on venereal diseases, leprosy and bone surgery; a delegate representing the Navy Department at the fifteenth International Congress of Hygiene and Demography and Second Pan American Scientific Congress; a member of the War Relief Board, American Red Cross, 1914-1917, of the General Medical Board of Council of National Defense, 1917, of the Board for Development of Navy Yard Plans, 1916, of the Interbureau Logistics Committee, 1916-1917, of the General Munitions Board organized at the outbreak of World War I; in charge of the exhibit of the Medical Department of the Navy at the sesquicentennial exhibition, Philadelphia, which was awarded a gold medal; member of the American Association for the Advancement of Science, American Association of the History of Medicine, American Social Hygiene Association, Association of Military Surgeons of the United States and the American Public Health Association; fellow of the American College of Surgeons; senior medical officer for the V-12 program at the University of Pennsylvania; died suddenly in Darby April 2, aged 70, of edema of the lung.

Francis Rivers Lawther, Wilmington, N. C.; University and Bellevue Hospital Medical College, New York, 1934; member of the American Medical Association and the South Carolina Medical Association; fellow of the American College of Surgeons; interned at the Bellevue and Roosevelt hospitals in New York, where he served a residency at the Memorial Hospital for the Treatment of Cancer and Allied Diseases; served as medical director of the Berkeley County Hospital in Moncks Corner, S. C.; commissioned a captain in the medical corps, Army of the United States, on May 21, 1942; later promoted to major; chief surgeon at Kelly Field, Texas; killed in an airplane accident in Tucson, Ariz., January 20, aged 37.

Carl Henning Mattson ⊕ St. Paul; University of Minnesota Medical School, Minneapolis, 1930; served an internship and residency at the Ancker Hospital; began active duty as a lieutenant commander in the medical corps of the U. S. Naval Reserve on Sept. 24, 1943; died in the Pacific area, January 15, aged 43, of a generalized gasoline burn received in a plane crash while on his way back to the Admiralties following his participation in the Luzon invasion.

Frank Hugh Maxwell ⊕ Mansfield, Ohio; University of Michigan Medical School, Ann Arbor, 1930; served an internship at St. Luke's Hospital in Cleveland and a residency at the Mansfield General Hospital; began active duty as a captain in the medical corps, Army of the United States, on April 26, 1942; died in Mindora, P. I., March 7, aged 39.

Ned Robert McKrill, Weston, Mass.; Tufts College Medical School, Boston, 1942; diplomate of the National Board of Medical Examiners; served an internship and residency at the Charity Hospital in New Orleans; began active duty as a lieutenant (jg) in the medical corps of the U. S. Naval Reserve on Oct. 10, 1944; accidentally drowned in the Pacific area February 1, aged 30.

Samuel Fletcher Parker ⊕ Colonel, M. C., U. S. Army. Jackson, Miss.; Hospital College of Medicine, Louisville, Ky., 1905; served during World War I; entered the medical corps of the regular U. S. Army as a major in 1920; promoted to lieutenant colonel in 1937; later promoted to colonel; stationed in Hawaii for six years; in 1925 was transferred to Western Reserve University School of Medicine in Cleveland, where for five years he was professor of military science and tactics; chief of the pediatric service at the Army General Dispensary in Washington, D. C., from 1930 to 1935 and chief of the outpatient department at Walter Reed Hospital from 1939 to 1941; chief of the medical service at Fort Monroe, Va., from 1935 to 1937, serving in the same capacity at Gorgas Hospital in Ancon, Canal Zone, from 1937 to 1939 and at La Garde General Hospital, New Orleans, from 1941 to 1943; supervised the building of Foster General Hospital, becoming its first commanding officer in 1943; died in the Kennedy General Hospital, Memphis, Tenn., February 6, aged 62, of heart failure following pneumonectomy.

Warren David Robbins, Cape May, N. J.; Cornell University Medical College, New York, 1926; member of the American Medical Association; past president, secretary and treasurer of the Medical Society of Cape May County; diplomate of the National Board of Medical Examiners; served as county physician and police surgeon; interned at the Philadelphia General Hospital and served a residency at St. Christopher's Hospital for Children, Philadelphia; began active duty as a captain in the medical corps, Army of the United States, Sept. 21, 1942; died in Italy Aug. 9, 1944, aged 43, of acute subarachnoid hemorrhage.

Robert Sanderson ⊕ Arlington, Va.; Harvard Medical School, Boston, 1932; member of the Massachusetts Medical Society; diplomate of the National Board of Medical Examiners; interned at the Beverly Hospital in Beverly, Mass., and the Boston City Hospital; commissioned a lieutenant in the medical corps of the U. S. Naval Reserve on Aug. 8, 1942; stationed in the Navy Department in Washington, D. C.; died February 21, aged 41.

Karl McCormick Scott, Lakewood, Ohio.; University of Michigan Medical School, Ann Arbor, 1912; member of the American Urological Association; served during World War I and later in the regular U. S. Navy; commissioned a lieutenant commander in the medical corps, U. S. Naval Reserve, on July 8, 1944; died in the U. S. Naval Hospital, Portsmouth, Va., Sept. 29, 1944, aged 54, of atrophic cirrhosis of the liver.

IRREVERSIBLE ORGANIC CHANGES IN CASES OF PSYCHIATRIC DISTURBANCE

To the Editor:—Col. Howard A. Rusk, chief of the Convalescent Service Division, Office of the Air Surgeon, Army Air Forces, has referred to us the following problem:

"From observations in the field of 'operational fatigue,' stress reaction, anxiety state from combat and so on, there are certain endocrinologic and physiologic changes, some of which are apparently irreversible even after the psychiatric problems have been adequately treated. All pertinent data on this subject with its interpretation by experts in the field, research projects and any other material or work that could be undertaken to increase the knowledge in this field would be deeply appreciated."

I would welcome any further citations in this field.

Sincerely yours,

DAVID R. SALMON, 1775 Broadway, New York 19.
Executive Director, National
Council on Rehabilitation.

TESTS FOR URINARY BILIRUBIN

To the Editor:—After reading the editorial entitled "Methylene Blue Test for Urinary Bilirubin" in THE JOURNAL, April 21, it seemed probable that a practical solution of the clinical problem of detecting small amounts of bile in the urine had been attained. According to the recent article by Myers (*J. Indust. Hyg. & Toxicol.* **27**:52 [Feb.] 1945), whose work is based on that of Franke and of Fellinger and Menkes (*Wien. klin. Wchnschr.* **46**:133 [Feb.] 1933), when 2 drops of Loeffler's methylene blue are added to 10 cc. of urine containing bilirubin the urine turns a brilliant green. Consequently the occurrence of such a "positive" test with the second normal urine specimen which we tested according to directions was disturbing. As the specimen, though containing no bile, was a concentrated, yellow sample from a normal subject, it appeared to be possible that the "positive" test was entirely nonspecific for bilirubin.

That a chemical reaction with bilirubin is clearly not involved was demonstrated by the fact that "positive" tests were observed whenever distinctly yellow but bile free specimens of urine from normal persons were tested according to Myers' directions. Moreover, when a bile containing urine was diluted with water to the same strongly yellow color as that of a concentrated normal urine containing no bile, the addition of methylene blue to each gave identical green colors. Finally, various shades of green were obtained with solutions of such different blue pigments as Loeffler's methylene blue, brilliant cresyl blue or prussian blue in such yellow or reddish yellow liquids as meat infusion broth or aqueous solutions of potassium dichromate, ferric chloride, istizin (dihydroxyanthraquinone) or hemolyzed blood.

Fellinger and Menkes, as well as Myers, expressed uncertainty but recognized that the test probably depended on a mixture of pigments. That such an optical effect was largely, if not wholly, responsible for the change of color of these dyes from blue to green when placed in the yellow liquids was made clear by the following simple experiment:

Ten cc. of distilled water was placed in a test tube, and in two similar test tubes were placed 10 cc. of one of the aforementioned distinctly yellow liquids. To one of the tubes containing the yellow liquid were added 2 drops of Loeffler's methylene blue. To the tube containing distilled water was added the same amount of dye. Now, when the test tube containing the blue dye in distilled water was viewed in daylight through the test tube containing the yellow liquid, it appeared to have exactly the same green color as did the tube of yellow liquid to which the blue dye had been added directly.

According to Myers, "the only known false positive tests encountered in these tests were found in urine containing blood and in several cases where there was an elevated temperature above 101 F." A few drops of blood hemolyzed in 10 cc. of distilled water give a yellowish red solution with slight turbidity. The urine of febrile patients is often concentrated and yellow or yellowish red. Istizin, an orange-yellow cathartic drug, when secreted in the urine also gives a false positive according to Fellinger and Menkes. However, from our experiments it appears that any sufficiently yellow liquid or urine, whether containing bilirubin or not, will give a "positive" test. Consequently it is disappointing to be forced to the conclusion that the methylene blue test merely substitutes, for the problem of whether a urine is more or less yellow, the equally subjective question as to whether after the addition of methylene blue the sample of urine appears more green than blue. Unfortunately for the usefulness of the test in the clinic, bilirubin is only one of several substances which may impart, when present in sufficient concentration, a yellow color to normal or pathologic urines.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Alleged Failure to Sterilize Open Wound Before Placing Fractured Leg in Cast.—The plaintiff, a boy of 19, was struck by an automobile in Virginia, Jan. 17, 1942, and was thrown into a sandy ditch, suffering a compound comminuted fracture of the right leg, just below the knee. He was taken to a hospital in Williamsburg and given temporary attention. January 19 the defendant physician, who "specializes in bone and joint surgery," took charge of the case. According to the plaintiff there was an open wound in his lower leg with the broken bone protruding, and the defendant did nothing to sterilize or cleanse the wound except to wipe off the blood and then immediately put on a closed cast extending from the patient's toes to his groin. Thereafter gravel, sand and pus came out from the cast at the top at the groin. Eighteen days after the application of the cast the patient's brother-in-law cut an opening in the cast over the wound, and pus and sand came from the opening. Subsequently the defendant placed another cast on the leg and left a window in it for dressing. The plaintiff returned to his home in North Carolina March 6 and consulted other physicians, who on April 5 performed an operation on the leg, removing pieces of bone. Apparently on the back of the leg along which the pus had run the epidermis had been damaged or removed as a result of a maliguant infection that had set in. Eventually the right leg became about an inch shorter than the other. Subsequently the patient instituted an action for malpractice against the defendant, alleging that the physician failed to use reasonable care and diligence and failed to exercise his best judgment and skill in treating him, resulting in increased pain to the patient, necessitating the operation performed in North Carolina, and causing the shortening of the leg. At the trial there was medical testimony that a failure to disinfect and cleanse the wound and limb would be improper treatment, that it would not be proper to put a cast on the leg without sterilizing the wound and that failure to sterilize an open wound with sand in it would tend to set up or increase infection. Evidence was presented on behalf of the defendant tending to show that he had properly cleaned and sterilized the wound and had treated his patient in the best approved manner. At the close of the evidence the trial court sustained a motion for a nonsuit and dismissed the action. The patient then appealed to the Supreme Court of North Carolina.

The only question presented, said the supreme court, is whether or not there was sufficient evidence adduced at the trial to require the submission of the case to the jury. On a motion for judgment of nonsuit the defendant's evidence cannot be considered unless favorable to the plaintiff, and the plaintiff is entitled to every fact and inference of fact pertaining to the issues involved which reasonably may be deduced from the evidence. The plaintiff was injured in Virginia and was treated by the defendant in that state. It follows therefore that in an action for damages for malpractice the standard of the physician's duty in the premises as affecting his liability for negligence must be determined by the law of the place in which the tort complained of was committed. The court accordingly cited a number of applicable decisions of the Supreme Court of Appeals of Virginia and from them concluded that the pertinent law in Virginia is as follows: A physician is bound to bestow on the treatment of his patient such reasonable and ordinary skill and diligence as those practicing in the same general line ordinarily exercise in like cases and one who accepts employment as a specialist must not only possess that degree of skill and knowledge ordinarily possessed by those engaged in that specialty but must also exercise his best judgment in the application of his skill and in the use of ordinary care. That degree of skill and care is to be exercised both in the performance of the operation and in the subsequent necessary treatment following. A physician, however, is not an insurer of a cure or even of beneficial results, nor is he held to the highest degree of care known to his profession. The mere fact that his treatment was not successful or was deleterious will not alone raise a presumption of negligence. The physician must exhibit only that degree of skill and diligence employed by the prudent practitioner in his field. The standard for the measurement of the skill exercised is to be shown largely by the testimony of expert witnesses, and where there is conflicting testimony of the expert witnesses as to the standard of professional skill and care, as well as to the ultimate facts on which the expert evidence is based, a question for the consideration of the jury is presented.

The principles just announced, continued the North Carolina court, are not in conflict with the standards of professional conduct established by the decisions of this court. For instance, it has been repeatedly held in North Carolina that a physician who undertakes to treat a patient implies that he possesses the degree of professional learning, skill and ability that others similarly situated normally possess; that he will exercise reasonable care and diligence in the application of his knowledge and skill to the patient's care; and exert his best judgment in the treatment and care of the case entrusted to him. *Nash* v. *Royster*, 189 N. C. 408, 127 S. E. 356; *Covington* v. *Wyatt*, 196 N. C. 367, 145 S. E. 673; *Lippard* v. *Johnson*, 215 N. C. 384, 1 S. E. (2d) 889. Accordingly this court has held that a physician may be held liable for an injury to his patient only when the injurious result flows proximately from want of that degree of knowledge and skill ordinarily possessed by others of his profession, or from the omission to exercise reasonable care and diligence in the application of his knowledge and skill to the treatment of his patient. *Davis* v. *Wilmerding*, 222 N. C. 639, 24 S. E. (2d) 337; *Groce* v. *Myers*, 224 N. C. 165, 29 S. E. (2d) 553. Specifically in the Davis case, supra, this court said:

> A departure from approved methods in general use, if injurious to the patient, suffices to carry the case to the jury on the issue of negligence.

Inferences of want of due care may be drawn from evidence tending to show that harmful foreign substances were introduced into a patient's body during surgical operations and left there. *Pendergraft* v. *Royster*, 203 N. C. 384, 166 S. E. 285; *Mitchell* v. *Saunders*, 219 N. C. 178, 13 S. E. (2d) 242. Applying these principles, it is apparent that, while there was no evidence adduced at the trial that the physician defendant did not possess requisite knowledge and skill in his profession, the plaintiff did offer some evidence of negligence on the part of the defendant with respect to his failure to cleanse and sterilize the open wound before applying the closed cast.

The physician, however, sought to justify the action of the trial court in sustaining a nonsuit on the ground that there was no substantial evidence that any negligence in this respect was the proximate cause of the result complained of. While all of the injurious results, answered the court, complained of may not be attributed to the negligence of the attending physician, if established, we think there is some evidence tending to show that suffering on the part of the patient was aggravated, another operation necessitated, and the epidermis on the patient's leg removed as a result of malignant infection set up or increased by the physician's want of due care as alleged. While the physician's evidence tended to deny the facts alleged by the patient, as well as the inferences and conclusions therefrom on which the patient's action was based, we think there was sufficient evidence produced to warrant submission of the case to the jury and that the trial court was in error in granting the motion for nonsuit.

Accordingly the judgment in favor of the physician was reversed and the case remanded for a new trial.—*Buckner* v. *Wheeldon*, 33 S. E. (2d) 480 (N. C., 1945).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Diseases of Children, Chicago

Hemorrhagic Uremia. M. G. Peterman.—p. 103.
Congenital Ileal Atresia with Gangrene, Perforation and Peritonitis in Newborn Infant: Staged Operations: Obstructive Resection, Ileocolostomy and Excision of Exteriorized Ileum. E. E. Arnheim.—p. 108.

Immunity to Tetanus.—Peshkin administered to 25 allergic children, four years after completion of the basic immunization with two 0.5 cc. doses of combined alum precipitated diphtheria and tetanus toxoids, a third, or "booster," dose of 0.5 cc. of alum precipitated tetanus toxoid alone. No febrile or systemic allergic reaction occurred. Prior to the administration of the "booster" dose and from one to six months thereafter, reactions to scratch tests with undiluted combined alum precipitated diphtheria and tetanus toxoids and with alum precipitated tetanus toxoids alone gave negative results. The injection of a third or "booster" dose was followed in all instances within one month by an adequate tetanus antitoxin titer. This titer was always higher and lasted for a much longer period than that which followed basic immunization as well as that which followed administration of a "booster" dose three to fifteen months after basic immunization. The titer was comparable to the maximum antitoxin response following a "booster" dose of toxoid given two years after the basic immunization. The highest antitoxin values thus far obtained followed a "booster" dose injected three years after the basic immunization. In a child with basic immunization with two doses of combined alum precipitated diphtheria and tetanus toxoids, the third injection to be administered two to four years later should be of alum precipitated tetanus toxoid alone in order to keep local and systemic allergic reactions at the minimum level.

Erythroblastosis Fetalis in Mothers with Rh Positive Blood.—Polayes reports 2 cases of erythroblastosis in detail. The 2 fulfil all the clinical criteria for the diagnosis of erythroblastosis fetalis (icterus gravis neonatorum). One patient recovered after a transfusion of blood; the other died despite similar therapy. Necropsy showed the anatomic changes of erythroblastosis fetalis, including kernicterus. In both cases the mother's blood group was group O, Rh positive and the child's group A, Rh positive. The Rh factor and all its known variants, as well as the Hr antigen, were excluded as possible immunizing antigens. In both cases the anti-A agglutinin in the mother's serum showed a high titer (1:700 and 1:750), a fact which strongly suggests isoimmunization of the mother with the A antigen of the baby. Although more statistical data are required to establish the frequency of such cases, nevertheless it is believed that (*a*) isoimmunization by the A and B agglutinogens may occur and that (*b*) erythroblastosis fetalis may result from A or B isoimmunization by a mechanism similar to that already established for the Rh factor.

*Calcific Aortic Valve Stenosis: Clinicopathologic Correlation of 22 Cases. N. E. Reich.—p. 234.
Aneurysms of Abdominal Aorta. J. Epstein.—p. 252.

Implantation Therapy of Addison's Disease.—Kemper recommends a daily dose of from 3 to 6 Gm. of sodium chloride and elimination of foods rich in potassium. If the patient is not able to carry on in his usual occupation, daily injection of desoxycorticosterone acetate should be begun until the adequate daily dosage is determined. Sodium chloride treatment should be continued. Within two or three months just enough pellets should be implanted to meet the patient's calculated need. It has been determined that one pellet of desoxycorticosterone acetate, weighing 125 mg., when implanted under the skin, gives off approximately 0.5 mg. of the hormone in twenty-four hours. If the patient's daily dosage requirement has been determined to be 5 mg. of the steroid compound, it will require implantation of ten pellets to meet his daily hormonal needs. The sodium chloride treatment should be continued. Pellets should be reimplanted about once a year. De Maio suggests implantation by means of a small trocar and glass rod obturator. The method reduces the length of the skin incision and simplifies the implantation technic. Symptoms that may develop because the implanted pellets fail to regulate the carbohydrate metabolism should be corrected by dietary supervision and supplemental adrenal extract injections. The complication of crises should be met by supplemental sodium chloride, adrenal extract and additional synthetic hormone.

Calcific Aortic Valve Stenosis.—Reich studied 22 necropsies in cases of pure calcific aortic valve stenosis found at Kings County Hospital from 1934 to 1942. Rheumatic fever and arteriosclerosis have been established as the etiologic factors. Subacute bacterial endocarditis with calcification is a rarer cause. The occurrence was four times greater in males than in females in the rheumatic group. Arteriosclerotic involvement occurred seven times more frequently among males. Dizziness and syncope were due to cerebral anemia. The anginal attacks were due to myocardial ischemia. Left ventricular failure manifested itself frequently in varying degrees of dyspnea. Reasons for the failure to make an accurate diagnosis were the misinterpretation of the murmur, the confusion caused by the presence of other murmurs and the lack of corroborative findings, such as a systolic thrill and absence of an aortic second sound. The presence of apical murmurs during systole was either due to transmission from the base or due to a relative mitral insufficiency caused by the dilatation of the left ventricle. Presystolic murmurs at the apex were of the Austin-Flint type. The pulse pressure was usually normal or decreased but was sometimes increased because of concomitant aortic regurgitation or hypertension. Clinical enlargement of the heart closely paralled the weight, which was increased considerably. Fluoroscopy and roentgenographic examination is capable of almost doubling the frequency of diagnosis. Left axis deviation and

T wave negativity were helpful in differentiating aortic insufficiency and mitral lesions, since these tend to produce hypertrophy in the right chambers as well, with resultant right ventricular strain The degree of calcification closely paralleled the degree of stenosis. Cardiovascular and extracardiovascular causes of death were about equally divided. In the absence of hypertension and definite mitral valve involvement a systolic murmur at the aortic area should suggest calcific aortic valve stenosis.

Convulsive Factor in Commercial Penicillin.—Walker and Johnson found that application of commercial penicillin to the cerebral cortex of cats, dogs, monkeys and human beings has given rise to convulsive manifestations The antibiotic and convulsive factors of penicillin appear to be closely related, for they are affected about equally by aging, boiling and acidifying the penicillin solution and by dissolving the penicillin in alcohol. In human beings penicillin applied to the cerebral cortex in doses of 10,000 to 20,000 Oxford units may produce convulsive manifestations

Effect of Vitamin E on Impaired Kidney Function.—Shute presents observations on 13 women who gave evidence suggesting either chronic nephritis or impaired renal function, such as chronic edema not cardiac in nature or hypertension. In some of the women the impairment of the renal function followed toxemia of pregnancy. Whenever possible two separate tests of the kidney function were made before treatment was begun. Therapy consisted in two weeks' trial of 25 mg. synthetic alpha-tocopherol per day. At the end of the two weeks the two hour test was repeated and the patient examined for clinical improvement Benefit was obtained in 10 of the 13 women. The histories which are presented indicate that treatment with vitamin E may improve damaged kidney function even when the damage has been of some duration. The improvement develops quickly but is transient unless therapy is continued

Vaginal Smear in Diagnosis of Uterine Cancer.—Fremont-Smith and his associates report 813 cases in which Papanicolaou's vaginal smear method for diagnosis of uterine cancer was employed. Negative smears were obtained in 635. The rest were either positive or doubtful. Cancer of the uterus can be diagnosed by vaginal smear even in the early stage. The method is applicable to the screening of large numbers of women. A negative smear does not exclude cancer. A positive smear usually means cancer. In the presence of a positive smear a biopsy should be done immediately, even though there is no clinical evidence of cancer. The diagnosis of the smears is not easy. It is not an office procedure. Familiarity with the vaginal cytology is important, and training in a laboratory doing this special work is essential.

New Sound Tip for Cystoscope. W. W. Scott.—p. 263

Carcinoma of Prostate.—The 40 cases presented by Stirling are divided into 4 categories: (1) those in which orchiectomy was performed, (2) those in which orchiectomy preceded or followed resection, (3) those in which resection, orchiectomy and diethylstilbestrol were combined and (4) those in which diethylstilbestrol was used. Of 4 patients subjected to orchiectomy 2 responded favorably and lived at least two years. A third patient was bedridden and had extensive metastases to the sacrum and lumbar vertebrae. He had lost 30 pounds (14 Kg.), was anemic and suffered intense pain. Within seventy-two hours after orchiectomy the pain became less, and within a week he was able to return home without taking an opiate. He died nine months later. The fourth patient died four months after orchiectomy from cachexia. The second group, in which resection preceded or followed orchiectomy, comprised 18 patients. Ten of these succumbed after an average survival of fourteen months, but none of these 10 died from prostatic causes. Early favorable responses were obtained. Of the 8 surviving patients, 5 were entirely relieved of their pain, 2 were partially relieved and 1 obtained no relief. The third group in which resection, castration and diethylstilbestrol was used comprised 12 patients, 10 of whom are living. This is the most favorable survival group in the entire series. The 2 patients who died survived for an average period of twenty-four months following operation. They were relieved of the pain but died from cachexia. In the fourth group of 6 patients for whom estrogen therapy was used alone, 3 patients are living and 3 are dead. The author concludes that castration and estrogen therapy seem to be palliative. Neither modality prevents recurrence or retards metastasis. Resection should be utilized when partial or complete obstruction of urination is encountered. Estrogen therapy is indicated for patients refusing castration or as a supplement to orchiectomy.

Equine Encephalomyelitis of Virus Type.—Randall maintains that equine encephalomyelitis is the most important horse disease in the United States at the present time. The knowledge that the three types of equine encephalomyelitis enzootic in the Western Hemisphere (eastern, western and Venezuelan) are pathogenic for human beings and the relatively high mortality rate of the human disease emphasize their importance from the public health standpoint. The evidence is ample that the disease is transmitted through insects, particularly mosquitoes, and its control involves antimosquito measures. Horses and mules may be protected against the disease by the annual administration of chick tissue vaccines. A vaccine suitable for human use can be made available if indications for its use develop.

Hematology (concluded). W. Dameshek.—p. 280

Burns in Diabetes Mellitus.—Root describes the metabolic changes which accompanied serious burns in 2 diabetic patients. A woman aged 66, who had undergone two leg amputations and who had diabetes of the typically mild degree often associated with gangrene, had not taken insulin regularly because her urine was sugar free with diet alone. The fasting blood sugar level had varied from 110 mg. to 210 mg. She entered the Deaconess Hospital with a second degree burn on the right arm and a large eschar on the left buttock. The blood sugar level was 480 mg. She received 195 units of insulin in the first two days. At first the burns showed no evidence of serious sepsis, but this later developed and she died

on the nineteenth day. A man aged 35 had had diabetes for fifteen years, which likewise was mild and controllable by diet. As the result of a severe sunburn on the shoulders and back the skin became infected, with the formation of multiple carbuncles. He developed phlebitis and osteomyelitis and later prostatic and paranephric abscesses. When hospitalized he had to be given insulin. During the period when he suffered severe sunburn and carbuncles developed, his diet was not weighed or measured and the urine was not sugar free. The failure to control the diabetes may well have been an important factor encouraging the spread of infection.

Aseptic Antepartum Thrombophlebitis.—Aseptic antepartum thrombophlebitis was observed by Steiner in a woman aged 36. The number of reported cases (17, including the 1 reported) is too small for significant analysis. Both unilateral and bilateral involvement occurred and both the saphenous and femoral veins with their branches were affected. Fever was seldom a part of the picture, and the diagnosis of aseptic thrombophlebitis (phlebothrombosis) was warranted. Recovery was usually complete, though not all patients went to term. The author's case differs from most of the reported cases in the early onset of the complication at the end of the third month of pregnancy, when the uterus, although enlarged, is not yet large enough to cause much pressure on the pelvic structures. The only factor in the history which can be related to the development of thrombophlebitis was the prolonged period of rest in bed to avert a threatened abortion.

Bone Infections Treated with Penicillin.—Higley and Rude used penicillin in 25 cases of bone infection, in some of which there were old chronic infections; in these the response was not dramatic, although in the majority there was a decrease in drainage, with improvement in the general physical condition. In some of the cases it was possible to do elective surgery concurrent with the administration of penicillin, with no extension of the infection. In the acute cases which proved susceptible to penicillin, clinical improvement preceded the x-ray signs of healing and clinical recovery occurred. The authors present summaries of 6 cases which represent several types of bone infection in which definite improvement followed the use of penicillin. In general the treatment of bone infections with penicillin has been satisfactory. The response varies in individual cases. In most instances the period of active infection was considerably decreased. Roentgenographic studies in the treated cases revealed apparent arrest of the spread of the infection, with little or no sequestration of bone and little or no involucrum. There was evidence of healing, in the form of a reactive recalcification throughout the cortex of the bone, approaching the normal architecture of the bone much more closely than does the ordinary involucrum in osteomyelitis. The area of recalcification was of slightly greater density than normal bone. Since the progress of the infection was apparently arrested and the reparative process began before extensive spread, sequestration and involucrum had appeared, the resultant end sclerosis was less than has been commonly seen in extensive osteomyelitis.

Fever Therapy with Foreign Protein in Neurosyphilis.—Smith and his collaborators present the histories of 19 patients with dementia paralytica who were treated with intravenous triple typhoid vaccine. The average number of fever bouts per individual was ten. Except for those treated during 1943, no attempt was made to insulate during fever; in 1943 only blankets and hot water bottles were used. During 1944 a cradle and light technic has been developed. Ninety patients were treated with hyperpyrexia induced by intravenous triple typhoid vaccine. About 750 episodes of fever have been given, and untoward reactions have been of minor nature with the exception of a fatality in a man with moderately advanced dementia paralytica and hypertension. Of the 19 patients whose condition is described, 16 have shown clinical improvement.

Penicillin in Treatment of 1,455 Cases.—Penicillin has been used at the Bethesda Medical Center in 1,455 cases. Gonococcic infections numbered 740 and syphilis amounted to 324. Of this number 250 were early cases and 237 of these remain symptom free. Of the remainder 7 have had evidence of relapse while 6 have had what appear to be new infections. The other 87 have been instances of latent infection or central nervous system involvement. The results with penicillin in gonorrhea, early syphilis and infections due to streptococci and staphylococci are better than with any drug hitherto available. Penicillin appears to be on a par with the better sulfonamides in the treatment of infections caused by pneumococci. The usefulness of penicillin in meningococcic meningitis is not yet clearly defined. The throat cultures became negative for hemolytic streptococci within two to five days in the 14 cases of scarlet fever that were treated with penicillin. Subjective improvement was noted in two or three days. Three patients with erysipelas responded promptly to penicillin. Penicillin, administered for stomatitis and Vincent's angina, gave good results. Penicillin has been used in 36 cases of acute otitis media and acute mastoiditis with satisfactory results. Penicillin is the drug of choice in abscess complicating pharyngeal and laryngeal infections, and it was effective in 2 cases of corneal ulcer. Penicillin was used in 32 cases of surgical infections, that is, in cellulitis, postoperative infected wounds, infected hematoma, infected surgical wounds and bullet wounds. Its use was successful in 27 cases. Of 29 cases of osteomyelitis 24 were successfully treated with penicillin. Penicillin has been used in 7 cases of peritonitis associated with ruptured appendix. All recovered from this complaint, although 1 patient died of a pulmonary embolus. Penicillin was found to be ineffective in tuberculosis, lymphosarcoma, carcinoma, infectious mononucleosis, chronic ulcerative colitis, leukemia, brain tumor, primary atypical pneumonia, rheumatic fever, malaria, filariasis and mumps.

Proflavine Powder in Burns.—Raven uses powdered proflavine for burns. Treatment is carried out under aseptic conditions. Contaminants are mopped away with isotonic solution of sodium chloride and pieces of dead tissue are lifted off. Normal skin surrounding the wound is cleansed. Blisters are evacuated by pricking with a sterile needle. Dry proflavine powder is lightly smeared over the wound, the whole lesion being thinly coated. The area is covered with one layer of wide meshed gauze impregnated with petrolatum and over this two layers of wide meshed gauze with a liberal supply of absorbent cotton. The dressing is bandaged firmly to form a pressure dressing with either plaster of paris or calico bandages. After the first redressing the time interval between dressings is increased from ten to fourteen days. Proflavine powder is dusted on the wound at each redressing. Two illustrative cases are described. A comparison of these cases shows that the general condition of the patient treated with proflavine was much better and the toxicity much less than that of the patient who had received sulfonamides both orally and locally. Proflavine powder does not retard healing, and the healed area showed a remarkable freedom from scarring, the skin being supple and of excellent quality.

Urea and Sulfonamide Treatment of Escherichia Coli Meningitis.—A soldier received a penetrating wound of the brain. A meningitis due to Escherichia coli failed to respond to sulfadiazine and penicillin, but the patient recovered after receiving 2 Gm. of sulfadiazine and 30 Gm. of urea introduced into the stomach every four hours. Ecker says that combinations of sulfonamides and urea possess a bacteriostatic effect even in the presence of the sulfonamide inhibitor, para-aminobenzoic acid. Urea is a diuretic, so it is especially important to

maintain an adequate fluid intake in patients who are receiving it. The sulfadiazine level in the blood in this case ranged from 7 to 9 mg. per hundred cubic centimeters at a time when the patient was receiving 2 Gm. of sulfadiazine and 1.2 Gm. of sodium bicarbonate every four hours.

Allergic Reactions to Penicillin.—Barker presents 2 cases of skin reactivity to penicillin. The first patient was a medical officer, who noticed a pruritus of the face the day after he started dispensing penicillin. Two days later he went on leave and the irritation disappeared. On his return he continued to dispense the penicillin solutions, and within two days an acute dermatitis of the face and neck developed which was accompanied by edema of the upper and lower eyelids and a feeling of tightness of the rest of the skin of the face. Next day vesiculation with a serous exudate was observed on the chin. The patient stopped dispensing but continued laboratory work with penicillin. The rash subsided within a week. When all clinical signs of dermatitis had disappeared, patch tests were performed with a solution of penicillin. An eczematous reaction developed within twelve hours. The control with autoclaved penicillin was negative. The second patient was a soldier who developed a giant urticarial reaction on the trunk and the extremities after having received intramuscular injections of penicillin for four or five days. The urticaria persisted for four weeks. The patient was covered with large confluent wheals on the trunk and extremities and exhibited dermographism. Scratch and intradermal tests with penicillin produced an urticarial wheal. An autoclaved solution of penicillin did not have this effect.

Mumps Meningitis.—During the epidemic of mumps in the winter of 1941-1942 458 patients with mumps were admitted to the Blegdams Hospital in Copenhagen. Spinal puncture was performed on 372, or 81 per cent, of these patients. Spinal pleocytosis was observed in 235 (65 per cent). Of these 235 cases 106 presented meningitis and 129 presented latent meningitis with pleocytosis as the sole indication of the disturbance of the central nervous system. There was no age predisposition, and the two sexes were equally susceptible. The severity of parotitis and the presence of other complications did not influence the incidence of meningitis. Pleocytosis varied between 3,000 and 7,000 cells per cubic millimeter of spinal fluid; high cell counts were frequent also among the cases of latent meningitis. The pleocytosis was entirely or predominantly mononuclear. The proteins were not increased, or only moderately so, the spinal sugar was normal and the spinal fluid was sterile. Manifest meningitis appeared most frequently after the onset of the swelling of the parotid glands (up to thirty-eight days after, but mostly about the fifth day), occasionally simultaneously with, and in 10 per cent of the cases before the swelling (up to seven days before). The meningeal symptoms were mild and of short duration. Encephalitis and myelitis were not observed. One case showed involvement of the labyrinth. Unilateral deafness persisted. All the remaining patients were discharged without sequels. The immediate prognosis was always good. The high incidence of meningitis suggests that meningitis is to be considered as a manifestation rather than as a complication of parotitis. This suggestion is supported by the occurrence of the so-called prodromal forms in which the meningitis precedes the parotitis and by the autonomic forms of meningitis of parotitis virus etiology but without swelling of the parotid glands. Thirteen cases presenting benign lymphocytic meningitis of the latter type were admitted to the Blegdams Hospital during the aforementioned epidemic of mumps. The parotitis virus consequently seems capable of affecting the meninges as the single organ. Epidemic parotitis is therefore to be considered as a possible etiologic factor in cases of benign lymphocytic meningitis of unknown origin. Mumps is to be considered as a general infection whose essential clinical manifestation most frequently, but not necessarily always, is a swelling of the parotid glands.

Rhizomelic Spondylosis Associated with Peripheral Arthritis.—Dekkers reports experience gained from 120 cases of rhizomelic spondylosis at the Consulting Office on Rheumatic Diseases in Amsterdam during the decade of 1931 to 1940. Only 10 of the 120 patients were women. Nine cases presented rhizomelic spondylosis associated with peripheral arthritis. Six of these 9 patients suffered from gonorrhea. In 4 of these patients the rheumatic complaint started in connection with this infection or was aggravated by it. Two patients suffered from rheumatic fever and 1 from a subacute polyarthritis some time before the spondylosis developed. All these cases presented the clinical picture of rheumatoid arthritis, a relatively infrequent occurrence, which made diagnosis very difficult; in fact, many years had passed before the diagnosis was clarified. Dekkers emphasizes the importance of examining the spine also in patients suffering from acute or chronic polyarthritis, especially when the patient complains of low back pain. In doubtful cases the roentgenologic examination of the sacroiliac joints and of the spine should not be omitted. Stress is laid on the necessity of not overlooking an existing spondylosis in patients suffering from rheumatoid arthritis, especially when they do not react well to gold salt injections. X-ray treatment of the spine and of the sacroiliac joints in combination with physical therapy (ultraviolet light, heat applications, exercises) may be most effective.

Alcoholic Amblyopia.—Roe reports 16 cases of alcoholic amblyopia in 14 men between the ages of 24 and 69 and in 2 women aged 32 and 40. The action of methyl alcohol is due to inhibition of the process of oxidation caused by formic acid. This forms, by a reversible process, a complex compound with the iron in the respiration enzyme. Acidosis follows inhibition of the process of oxidation and is due mainly to lactic acid. Amblyopia does not as a rule appear till acidosis has become severe, i. e. sometime after the manifestation of general symptoms such as nausea, headache, dyspnea and vomiting. If the eyes are exposed to strong light, amblyopia may precede clinical signs of acidosis. Increase of metabolism favors acidosis and may thereby provoke amblyopia or may aggravate it if already present. A milder course of poisoning may be manifested if ethyl alcohol is consumed just before or after the drinking of methyl alcohol, the oxidation of which is thereby checked. All signs of poisoning may be averted if ethyl alcohol is drunk repeatedly on the first day after the drinking of methyl alcohol even though it has been consumed in large quantities. It is suggested that the intake of much fluid may exert a beneficial effect on the course of the poisoning. A secondary decline of vision was observed in all the cases in which normal acuity of vision was not restored while amblyopia persisted. It is suggested that this gradual decline and the gradual developing limitation of the field of vision may be due to atrophy of the blood vessels. Strong light, fever and muscular exertion may hasten this decline. The individual predisposition is believed to play a minor part in the tolerance to methyl alcohol. Treatment of alcoholic amblyopia consists in rapid correction of the acidosis, the supply of large quantities of fluid and the protection of the eyes against light. The author recommends administration of an isotonic (1.3 per cent) solution of sodium bicarbonate, the dosage of which may be calculated according to Van Slyke's nomogram. Liberal flushing with fluid to combat dehydration and to promote profuse diuresis is suggested. Isotonic solution of sodium chloride may correct any hypochloremia present. Ethyl alcohol helps to prevent a recurrence of acidosis. Gastric lavage should not be carried out till an intravenous injection of sodium bicarbonate has been given. There was no reliable evidence in support of the assumption that lumbar puncture may be beneficial in amblyopia. Treatment with sweat baths and thyroid seems to be contraindicated.

Book Notices

Savill's System of Clinical Medicine Dealing with the Diagnosis, Prognosis, and Treatment of Disease for Students and Practitioners. Edited by E. C. Warner, M.D., F.R.C.P. Twelfth edition. Cloth. Price, $9. Pp. 1,168, with 192 illustrations. Baltimore: William Wood & Company, 1944.

The present edition of this popular book has been carefully revised under the editorship of Dr. E. C. Warner, but the essential character of the book remains unchanged from Dr. Thomas Savill's original plan. For the reader who is not familiar with this type of organization, it is essentially directed at the symptoms presented by the patient, the illness from which he suffers and what can be done about it. Each chapter is divided into three parts: the symptom which may indicate disease of the organ or region under discussion and its differential diagnosis, the physical signs of disease in that region and the various methods used to elicit them, and finally the clinical classification of various maladies affecting that region and a summary of the routine procedure to be adopted. This arrangement is unique among textbooks in medicine and serves a useful purpose for medical students on clerkships and physicians in their practice. Apart from this special feature of organization the book contains much concise modern information commonly found in textbooks of medicine. Some of the newer aspects of medical progress have been added on hypertension and its mechanism, vitamin K, sulfonamide therapy, carotid sinus, effort syndrome, Rh factor, electroencephalogram and wartime entities such as immersion foot, frost bite and trench foot. Other revisions have been added in keeping with the progress of medicine since the last revision. The chapter on the central nervous system is particularly well done. However, the chief virtue of the book is its unique plan of organization and its value as a diagnostic aid. Generally the treatment given is not in keeping with our standard textbooks on medicine. It is poorly defined, lacks critical insight and is generally inadequate. For this reason its value to the reader is restricted to its diagnostic guidance, which is usually sound and in keeping with good medicine.

L'inhibition et la facilitation dans le système nerveux central et périphérique. Par Miguel Ozorio de Almeida, directeur du Laboratoire de physiologie de l'Institut Oswaldo Cruz, Rio de Janeiro. Les publications savantes de l'École libre des hautes études au Brésil, 1. Paper. Pp. 135. Rio de Janeiro: Atlantica Editora, 1944.

This volume is intended to be a critical presentation of what is known about inhibition and facilitation as basic functions of the central and peripheral nervous system. The bibliographic index of 258 publications presents only the most characteristic publications, omitting the better known classic treatises.

The introduction directs the attention of the reader to the process of inhibition as an essential factor in coordinated movements and in the adaptation of purposeful reactions. Inhibition and facilitation are the indispensable factors of the functions of correlation and integration. Only the most elementary facts can be understood from the antiquated aspect of being the positive results of excitation or stimulation. Twelve chapters, almost the whole volume, contain the facts pertaining to inhibition and facilitation presented in a truly enlightening, critical and evaluating manner, and fifteen pages deal with the theories of facilitation and inhibition. Chapter 1 discusses the literature on inhibition and facilitation in lower animals, chapter 2 the phenomenon of facilitation and inhibition of similar phenomena as observed in the nerves and muscles of vertebrates. The Wedensky effect regarding the conduction of faradic current in a narcotized nerve is discussed through twelve pages, but its nature remains largely obscure in spite of the work of Lorente de No and others. Chapter 3 deals with facilitation and inhibition in reflexes, demonstrated already in the classic experiments of von Goltz, clinically observed for the first time by Nothnagel and elucidated by the work of Sherrington, Bethe, Frölich and others. Facilitation and inhibition in the rebound phenomena in decerebrate rigidity and in reciprocal innervation are discussed in chapters 4, 5 and 6. Chapters 7 and 8 deal with inhibition in strychninization and in tonic reflexes. The action of higher centers on reflexes and on the activity of lower centers, constant inhibition and facilitation, reciprocal action of cortical centers and extinction are discussed in chapter 9. Chapter 10 is dedicated to the analysis of spinal shocks, as an interruption of the facilitation brought about by stimuli from higher nerve centers. In general the spinal shock results from the abolished normal equilibrium of facilitation and inhibition. In chapters 11 and 12 the author discusses the role of inhibition and facilitation in tonus and in conditioned reflexes.

Inhibition and facilitation in their phenomenologic diversity can be interpreted only as the result of variable mechanisms. So-called peripheral inhibitory nerves demonstrate basically the same properties of excitability as other nerves. The same nerves may serve inhibition as well as excitation. Inhibition does not depend on the properties of a peripheral nerve but results from the function of the central nervous system, of ganglionary centers, of neuromuscular junctions. General theories of inhibition are those of "interference," "assimilation" or "drainage." A "colloidal" theory supposes modifications of electrolyte concentration, another is based on the "refractory period." The "chemical" theory assumes the formation of inhibitory substances. It appears that the central nervous system displays functionally the same properties which characterize the peripheral nerves, but in complicated combinations.

This interesting and inspiring treatise terminates with the discussion of several modern morphologic conceptions of the process of inhibition and facilitation.

The Male Hormone. By Paul de Kruif. Cloth. Price, $2.50. Pp. 248. New York: Harcourt, Brace and Company, 1945.

According to the flyleaf, this book is supposed to tell the story of the discovery of the male hormone. Actually the reader will find comparatively little concerning the discovery of any hormone. If the reader is credulous, he will turn to hormones instead of vitamins to stimulate his sexual activities, relieve fatigue and make him a business tycoon.

The book is written in the inimitable style peculiar to the author. Sensitive readers may object to reference to the possibility that if Ponce de Leon in a search for the elixir of youth "had only had a few shots of testosterone" he would have "proceeded to make all the Indian maidens of the land of the blue Caribbean." Others will merely think it comical for an allegedly scientific work. It offers enthusiasm but not the caution necessary for such potent agents as hormones. Once again de Kruif relieves himself of his pent up emotions and frustrations. He states "When the medical big bugs were out to get me on the one-day syphilis cure. . . ." Is this a persecution complex?

Sex seems to be the predominant theme of the book. Early in the volume de Kruif admits worry concerning degeneration and presumably death; soon he weaves a story around the sexual properties of a hormone; then he concludes that he will continue taking methyltestosterone, a product known as the male sex hormone.

Here is a sample of de Kruifian science: "We know that both the St. Louis Cardinals and St. Louis Browns have won championships, supercharged by vitamins." Does the author know this? He insists that he will "go on supercharging myself with vitamins just to be on the safe side, since God has played the trick on us of putting not quite enough vitamins in our food, even on the best balanced diet."

The Council on Pharmacy and Chemistry of the American Medical Association, which the author admits early in the book "is an excellent body of men," is attacked for pointing out what the author himself admits in his writing, namely, that much of the material which he has used to argue his points is still in need of further investigation. The fact that the members of the Council must have sufficient facts, not theories or provocative suggestions, to recommend a drug may appear immaterial to him. While presenting the virtues of the male hormone, he fails to leave with the reader a clear impression that the male hormone like any other hormone will be effective only in certain individuals, not all, and that it alone will not prevent or cure all forms of tiredness, diseased blood vessels and other common problems. Too little attention is devoted to the many questions yet unanswered; for example, effects of overstimulating the body with blood vessels and heart just on the verge of col-

lapse; effects on other endocrine glands; effects of long continued use. Too frequently science has seen the enthusiastic promotion of substances at first claimed to be practically miraculous and harmless but which later are shown to be lacking in therapeutic efficacy and even to be harmful, especially when carelessly used.

Here is a writer who, "being only a reporter and not a doctor of medicine," becomes enthusiastic about an experiment on a horse, the outcome of which made him "feel more confident than ever" concerning experiments made on older men. After considering what he believes to be the possible virtues of "my hero, testosterone," he is disturbed apparently and writes:

> This simply scares me. This smacks of rejuvenation. This can't be so. This gives me a bad case of buck fever. It pulls my writing wallop. I can't let myself go. To be honest, I doubt my hero, testosterone, the rebuilder.
>
> This is my mood this snowy morning.
>
> I actually begin holding back and soft-pedaling other scientific facts, suggesting other astounding rebuilding virtues of testosterone. I sabotaged my hero. Well, let's out with those new facts now.

And he does.

We have then in this book an enthusiastic, if sometimes maudlin and premature, report on the possibilities, mostly sexual, of the so-called male hormone. Some of the unknown factors in the problem of the use of hormones remain to be solved; such trifles are lightly brushed over in this book. Those qualified to speak concerning endocrinology will say that the book is premature and will do more harm than good by circulation among the general population.

Familial Susceptibility to Tuberculosis: Its Importance as a Public Health Problem. By Ruth Rice Puffer, Dr.P.H., Tennessee Department of Public Health. Harvard University Monographs in Medicine and Public Health [No. 5]. Cloth. Price, $2. Pp. 106, with 9 illustrations. Cambridge: Harvard University Press; London: Oxford University Press, 1944.

The author has made an earnest and honest attempt to determine why certain persons fall ill with clinical tuberculosis and others do not, with the idea of applying the information to modern tuberculosis control measures. In the introduction she states that the majority of the population in many sections of the country become infected with tubercle bacilli before reaching adult life. Therefore, on the assumption that all adults are infected with tubercle bacilli, the possibility of familial susceptibility is discussed at some length. Chapters are devoted to such subjects as tuberculosis in siblings, in consorts, in parents and in children of the tuberculous, and the control of tuberculosis.

Valuable data from various studies are presented. Considerable emphasis is placed on the tubercle bacillus, but the question is frequently raised as to whether this alone is adequate to produce tuberculosis. That inherited susceptibility may be necessary to permit the development of clinical tuberculosis is discussed at some length. In the discussion of observation on those who have previously been in contact with contagious cases of tuberculosis, only persons who later have manifestations of gross lesions such as can be demonstrated by x-ray shadows or which cause illness are regarded as having developed tuberculosis. Little consideration is given to those who develop the disease to a lesser degree, the presence of whose lesions can be detected only by the tuberculin reaction or postmortem examination. All such persons actually have tuberculosis and must be considered along with those who fall ill or die.

Appropriate warning is issued of the great danger of exposure to contagious cases of tuberculosis. This applies to the known cases. In this connection the tuberculin reaction is not mentioned, which is the only accurate method of detecting the individuals who have been effectively exposed in any group. No mention is made of the vast areas in the United States where the infection attack rate has been reduced to 1 per cent or less annually, of the corresponding decline in morbidity and mortality of numerous whole counties where 10 per cent or less of the seniors in the high schools have been infected with tubercle bacilli or of the reports of the American Student Health Association, showing that only 18 per cent of college students have been infected and in many Midwestern and Western colleges and universities less than 10 per cent.

One explanation of the decline in morbidity and mortality from tuberculosis in this country is that many members of susceptible families have died, and therefore such families are greatly reduced in number. At this point one must take into consideration the vast educational program of the National Tuberculosis Association and other organizations, which has resulted in the protection of the community against infection with tubercle bacilli. Of no small significance is the almost complete eradication of tuberculosis in the bovine species. Not long ago the bovine type of tubercle bacillus was responsible for a sizable segment of both primary and reinfection types of tuberculosis among human beings in this country. If the dying out of families with familial susceptibility were capable of solving the tuberculosis problem one would expect a different situation in nations with large populations, such as China, than exists at present. There tuberculosis has been known to exist more than five thousand years, but illness and death from tuberculosis among the Chinese constituted a tremendous problem even before the present war began.

Good methods of tuberculosis control are presented, such as periodic examinations of contacts of contagious cases, including students of nursing and medicine; however, these are extremely limited. By more modern methods the disease can be practically controlled in any community without much worry about those who may have familial susceptibility.

Most of Dr. Puffer's work and analyses and references are from communities where tuberculosis is still rife, where nearly 100 per cent of the adult population is thought to be infected, a situation not greatly different from that found in many European countries at the present moment. In such places it is difficult to bring the important factors in tuberculosis control into the limelight. Under such circumstances her presentation is splendidly done. It would be fine if she could now make a similar study and publish the report of her observations from a few of the many counties in the United States where the tuberculosis mortality has been reduced to less than 10 per hundred thousand of population and where the infection attack rate among children, including those of high school age, has been reduced to one half or one third of 1 per cent.

Aids to Orthopædic Surgery and Fractures. By I. E. Zieve, M.A., F.R.C.S., Surgical Registrar, Charing Cross Hospital, London. Second edition. Cloth. Price, $1.75. Pp. 270. Baltimore: Williams & Wilkins Company; London: Baillière, Tindall & Cox, 1944.

In rewriting this volume, which Mr. Eric Crook of Charing Cross Hospital first wrote in 1929, Zieve discusses the effects of abnormal development, injury, inflammations and new growths on bones, joints, muscles and tendons. He discusses these same influences on the nervous system. Free reference has been made to such standard works as Watson Jones's "Fractures and Other Bone and Joint Injuries," McMurray's and Mercer's works on orthopedic surgery and Bankart's "Manipulative Surgery." The book was not intended to take the place of larger books on orthopedic surgery in general or those on special regions. Many recent American contributions to the subject are omitted. This, the smallest book on orthopedic surgery, can easily go in a side pocket. Some subjects are treated with no more than a definition. On the whole, the book is an excellent publication and is well worth the small investment.

Experimental Studies on the Toxicity and Potential Dangers of Trinitrotoluene (TNT). By W. F. von Oettingen, Principal Industrial Toxicologist, and others. From the Industrial Hygiene Research Laboratory, National Institute of Health. Prepared by direction of the Surgeon General. Federal Security Agency, U. S. Public Health Service, Public Health Bulletin No. 285. Paper. Price, 15 cents. Pp. 78, with 22 illustrations. Washington, D. C.: Supt. of Doc., Government Printing Office, 1944.

Trinitrotoluene has toxicity of a low order, but its manufacture and handling are not without risk to the health of the workers concerned. This series of studies raises a number of questions with respect to these hazards and brings their answers up to date by means of observations on animals and on man. The long debated question as to whether or not pure TNT is less dangerous to handle than an impure product is raised but not answered. This interim report is essential to all physicians concerned with the industrial hygiene of high explosives.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

GLUTAMIC ACID FOR EPILEPSY

To the Editor:—How effective is the glutamic acid therapy of petit mal? Please give the recommended dosage and any reactions or contraindications to its use. Where can it be obtained?

Howard F. Munro, M.D., Freeport, N. Y.

ANSWER.—Glutamic acid has been reported as effective in the therapy of petit mal, psychic equivalents and personality disorders in patients with epilepsy. Accurate statistics as to its value are not available; perhaps half of the patients not benefited by other means respond favorably to glutamic acid. It is not effective against major seizures and indeed may precipitate them unless the patient is receiving some other anticonvulsant. The usual procedure is to place the patient on diphenylhydantoin sodium in gradually increasing doses until symptoms of intolerance appear. Attention should be paid to hygiene and especially to getting the patient into athletic training. If minor seizures or irritability are still troublesome, glutamic acid may then be added in large doses. The average dose for an adult is 12 Gm. a day, but twice this amount may be given safely. The dose for children is roughly in proportion. As glutamic acid is a normal constituent of the diet and widely used as a flavoring, no toxic symptoms are to be expected even from massive doses. Some patients find glutamic acid slightly nauseating, however. Glutamic acid is manufactured by Parke, Davis & Company in 0.5 Gm. tablets.

THROMBOSIS OF OVARIAN AND RENAL VEINS

To the Editor:—What is the clinical picture in thromboses of the left ovarian vein with and without involvement of the left renal vein? I should think that such a condition would be relatively common following operations involving the ovary and oviduct or those involving the pampiniform plexus in the male.

William C. Stephenson Jr., M.D., Roanoke, Va.

ANSWER.—As far as is known, thrombosis of an ovarian vein produces no pathognomonic signs or symptoms. Occasionally a thrombosis is found in one and rarely in both ovarian veins at the time of operation for fibroids, ovarian cyst or other condition, yet questioning has failed to elicit any unusual symptoms which might be attributed to these thromboses. Likewise there seem to be no sequelae from the discovery of thromboses in an ovarian vein at the time of a laparotomy. Involvement of the left renal vein may produce signs and symptoms involving the kidney; however, thromboses of these small deeper veins rarely produce symptoms or symptom producing thromboses of the renal vein. Should such occur, however, grave symptoms of general sepsis with localizing symptoms toward the involved kidney will be definitely present.

FREQUENCY OF URINATION IN ELDERLY MAN

To the Editor:—A man aged 70 has polyuria. His father died at 73 of uremia and prostate trouble. The blood pressure of the patient is 150/90, and he weighs between 160 and 165 pounds (73-75 Kg.). He has had no sickness during life with the exception of malaria forty years ago. He is 6 feet (183 cm.) tall, of erect posture and well preserved. The polyuria is intermittent. Repeated examinations of the urine microscopically and chemically reveal no abnormalities. Recently he finds that, after sitting for awhile, on getting up he is urged to urinate; it appears that gravitation of the bulk of urine acts on the trigone and the desire to urinate is pressing. If something attracts his attention at that time the desire passes off. There is no pain in the bladder and no pain at urination. A report from a urologist indicates some hypertrophy of the prostate, especially the left lobe; the prostate is not painful on examination. There are no obstructions to urination, no dribbling, no retention or residual urine and no cystitis. The urologic consultant thinks that a neuropsychiatric condition may exist.

M.D., South Carolina.

ANSWER.—In the absence of any pathologic elements in the urine, the cause of frequent micturition may be difficult to determine. It would first be desirable to ascertain the exact amount of urine that is secreted during the day and night periods and the amount of fluid intake. An apparent polyuria may be excluded in this way. The absence of any pathologic elements in the urine, and the fact that the patient's frequency is greater when he is on his feet, would suggest an irritable condition at the vesical neck or in the prostatic urethra.

Roentgenographic studies of the urinary tract are not mentioned. These should be made, particularly to exclude the possibility of prostatic stones as well as stones in the bladder; such stones may exist in the presence of a normal urine. The possibility of chronic prostatitis should also be considered. If a study of the prostatic secretion on massage reveals prostatitis, massage and instillations into the deep urethra may relieve the frequency of urination.

In view of the fact that there is some hypertrophy of the lateral lobes of the prostate gland as determined on rectal examination, it is very possible that the median lobe is similarly enlarged. Frequent desire to urinate often is brought on by an enlarged median lobe of the prostate gland protruding into the lumen of either the bladder or the urethra. In such cases the urine may be quite normal. Enlargement of the prostate gland and consequent deformity of the bladder neck may cause dysfunction of the neck of the bladder during micturition; as a result a small amount of urine may escape into the prostatic urethra and cause a frequent desire to urinate. If cystoscopy and urethroscopy show definite hyperplasia and deformity of the neck of the bladder, a transurethral resection may be considered if other means of eliminating the symptoms have failed.

POSSIBLE FROELICH'S SYNDROME

To the Editor:—A boy aged 13 had undescended testes when born. They did not descend until he had received several doses of antuitrin, and they were very small, about the size of a navy bean. At 12 he weighed 155 pounds (70 Kg.). His mentality seems to be normal, as the state of Kansas gave him a 99 plus; he makes good grades at school and has an even temper. His secondary sex development is normal. He sticks to a job very well, eats well, has a good appetite, sleeps well, does not suffer from incontinence—in fact he seems to be normal in every way except that the testes are but little larger now than a small navy bean. His height is 63 inches (160 cm.) and his weight 160 pounds (73 Kg.). What is suggested to increase the size of the testes, and what are the prospects for increasing the organs to normal size?

M.D., Oklahoma.

ANSWER.—There is no hormone that will increase the size of the testis; the male sex hormone will, however, increase the size of the genitalia. It is not clear whether the boy has previously had male sex hormone or gonadotropins. Before any form of therapy is given, it would be well to get an x-ray of his skull for the possibility of detecting a pituitary disorder; he should also have a test made of the basal metabolic rate.

From the query it would appear that the boy may have Froehlich's syndrome. If this is so and the testes are atrophied he should be given male sex hormones, possibly 75 to 100 mg. per week in divided doses. This form of therapy may be continued until the desired results are obtained.

CONGENITAL HORSESHOE KIDNEY, RENAL CALCULI AND INFECTION

To the Editor:—I have a patient with a congenital horseshoe kidney. Hematuria is present and numerous small calculi are passed. The x-ray film shows several opaque shadows in the right renal silhouette. One of these calculi was analyzed; it contained calcium oxalate. Examination of the bladder urine revealed 12 to 15 pus cells, singly and in clumps, per high power field, a rare red blood cell, occasional medium sized round epithelial cells and no casts. The urine of the right kidney showed 25 to 30 pus cells, singly and in clumps, per high power field, a few epithelial cells and an occasional red blood cell. The urine of the left kidney showed a rare leukocyte, a rare small epithelial cell and rare red blood cells; no clumps of pus cells and no casts were found. Cultures of all samples of urine show Bacillus pyocaneus and a few gram positive cocci. The patient has received sulfathiazole and sulfadiazine, but there has been no improvement in his condition. His p_H has been 6. Kindly give me suggestions as to treatment of this patient.

M.D., New York.

ANSWER.—This patient obviously has a congenital condition which makes for a poorly draining kidney. Infection in the presence of multiple stones makes it absolutely impossible to treat this kidney successfully as far as the infection is concerned, at least until the stones have been removed. It cannot be said, however, that surgical removal is indicated, as there are many circumstances which must be known before this can be determined. The combination of infection and the presence of calcium oxalate stones is not an indication for the administration of large and intermittent doses of any one of the sulfonamide drugs or of any other type of urinary antiseptic, since they will be of benefit only for the period during which the drug is being taken. It would be better to see that this patient has large amounts of fluid to keep the urine at the p_H level of 6.

DISABILITY FOLLOWING POSTVACCINAL (YELLOW FEVER) HEPATITIS

A STUDY OF 200 PATIENTS MANIFESTING DELAYED CONVALESCENCE

COLONEL JULIEN E. BENJAMIN
AND
MAJOR RALPH C. HOYT
MEDICAL CORPS, ARMY OF THE UNITED STATES

Epidemics of jaundice have occurred among troops in the armies of many nations in the past. The French have referred to the disease as the "jaundice of camps," and the English have often called it the "jaundice of campaigns." Outbreaks of jaundice in civilian communities in this country and abroad have been well described. Jaundice of the usual so-called catarrhal type occurs frequently among troops of our armed forces. Such outbreaks are characterized by an incubation period of twenty to thirty days or less and a spread by contact.

The occurrence of large numbers of soldiers with jaundice at widely separated locations here and abroad, early in 1942, had certain characteristics differing from the well known infectious or catarrhal jaundice. Of special interest was the fact that the outbreaks were invariably associated with administration of certain lots of yellow fever vaccine. Noteworthy were the observations that incidences were reported simultaneously from locations widely separated from the Pacific to the Atlantic and from the North to the South and the absence of demonstrable contact between these units as well as the absence of secondary outbreaks in locations at which this type of jaundice had occurred.

The clinical course of the disease was strikingly uniform in the great majority of patients. It resembled closely so-called "catarrhal jaundice." The onset was gradual, or imperceptible, until the appearance of jaundice. The incubation period was from forty to one hundred and twenty days. Increased susceptibility to fatigue, anorexia, nausea, vomiting and diarrhea were among the prodromal symptoms. There was usually a normal temperature and leukocyte count, with occasional relative increase in the monocytes. Then there was noted darkly colored urine, lightly colored stools and yellowing of the skin and scleras.

The liver was enlarged in about 20 per cent of the cases. Bile pigments appeared in the urine and blood; the icterus index ranged from 15 to 200 or higher, the prothrombin levels were reduced and the results of liver tests indicated various degrees of disturbance of hepatic function.

The vast majority of cases were mild, with recovery in four to eight weeks. In a small number the disease was more severe, and there were a few deaths, a case fatality rate of approximately 0.2 per cent.

The chief pathologic lesions were those of acute yellow or red atrophy of the liver, with frank necrosis of liver cells in the central parts of the lobule. The process is a diffuse necrosis, varying in different parts of the organ, with little damage to the stroma. Fatty changes were inconspicuous. The livers were very small. Edema and inflammation were noted in the gastrointestinal tract, most pronounced in the cecum, and not infrequently the kidneys showed cholemic nephrosis.

Etiologic investigations served to exclude bacterial infection, any type of leptospiral infection or yellow fever in any form as causative factors. That the component of human serum in certain lots of vaccine administered may have carried an icterogenic agent is strongly suspected.

Doubtless the great majority of soldiers who had postvaccinal hepatitis recovered fully or sustained only slight hepatic damage. On the other hand there were some patients who were considered well enough to return to their army duties but who subsequently were found unequal to such demands and were rehospitalized. A study has been made of 200 soldiers returned from overseas because of failure to achieve satisfactory convalescence after postvaccinal (yellow fever) hepatitis.

CLINICAL ASPECTS

These patients had been in overseas hospitals for several months, and some still appeared definitely ill on their arrival five to nine months after their original attack of jaundice. As a group they were pale, thin, exhausted and utterly devoid of animation. Their reactions, mental and physical, were slow and indifferent. They had had no military training whatever since their original illness. Their complaints were (1) extreme weakness, (2) overpowering fatigue, (3) indigestion (for fatty foods), (4) anorexia, (5) pain (especially in the right upper quadrant), (6) nausea and vomiting, (7) backache, (8) nocturnal insomnia, (9) nervous irritability and tremor and (10) anxiety and apprehension (fear of recurrence of jaundice).

From Lovell General Hospital, Fort Devens, Massachusetts.

Pfc William A. Atchley and Miss Mary R. Shields rendered invaluable clerical assistance.

Read before the joint meeting of the Section on Practice of Medicine and the Section on Experimental Medicine and Therapeutics at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 16, 1944.

The following officers contributed valuable assistance in the appraisal of conditions observed in these patients touching on their individual specialties: Richard P. Stetson, Lieutenant Colonel, M. C., medicine; Duncan Whitehead, Lieutenant Colonel, M. C., psychiatry; Thomas B. Jones, Lieutenant Colonel, M. C., surgery; Arthur A. Thibodeau, Major, M. C., orthopedics; Theodore B. Bayles, Captain, M. C., arthritis; Harry L. MacKinnon, Captain, M. C., psychiatry, and Drs. Mandel Cohen, William Chapman and Chester Jones, Harvard Medical School.

Early in the study it was apparent that for purposes of study the patients could be divided into four main groups:

GROUP A (39 patients).—These patients showed every evidence of having recovered from their hepatitis during their long hospitalization overseas. Their complaints were indefinite, centering mostly about their digestive tracts and more particularly about their supposed inability to digest fatty foods, although investigation showed that their ideas as to what constituted fatty foods were for the most part erroneous. For these patients an extensive program of retraining and rehabilitation was instituted, with the result that all were returned to full duty. Laboratory studies indicated that normal hepatic function had been reestablished. This group, therefore, was considered as being made up of individuals who had completely recovered from their hepatitis during their long hospitalization overseas and who only were in need of rehabilitation. Fifteen patients were neurotic.

GROUP B (94 patients).—These patients appeared on physical examination to be exhausted, pale and underweight. They were wholly indifferent to war activities or any other topic. Two prominent symptoms were profound anorexia and pain in the right upper quadrant. This pain appeared either soon after eating or soon after attempting mild exercise, such as walking. Tests of liver function showed that varying degrees of hepatic dysfunction remained in only 4 cases, and 19 per cent had palpable, tender livers. The members of this group were considered to have prolonged convalescence. There were 40 patients with a neurotic background.

GROUP C (30 patients).—Investigation by the neuropsychiatric service yielded abundant evidence that these patients had been neurotic before their attack of hepatitis and in many cases before induction, and that they had developed psychoneurotic disabilities as a result of their prolonged illness. Their neuroses focused largely on their digestive tracts and embraced such typical symptoms as anorexia, nausea, vomiting and pain in various regions of the abdomen, or low back pain. Many of these men gave past histories of sensitive stomachs, and their appetites had been catered to since youth. These patients were considered as being disabled primarily by neuroses which had been activated by antecedent liver disease.

GROUP D (37 patients).—These patients were obviously sick. Although they were classified as ambulatory, many spent the major part of the day in bed because of extreme degrees of weakness and exhaustion. They suffered frequently from nausea and vomiting, precipitated either by the first bite of food, eaten without zest, because of profound anorexia, or by walking even a short distance. The vomiting observed was frequently explosive and urgent. Eight patients were considered to be neurotic.

Of particular interest in this group were tremor and extreme vasomotor disturbance. The former manifested itself by a persistent, coarse tremor of the hands and feet, which was much accentuated by the slightest muscular effort, such as shaking hands or making a fist. The vasomotor phenomena consisted of icy cold, dripping, red hands and feet. When these patients were examined in the erect posture it was not unusual for them to drip perspiration from the tip of each finger.

Only 10 patients in this group still had evidence of hepatic insufficiency according to the results of serial sulfobromophthalein tests at thirty minutes. (Fourteen patients showed retention of 10 per cent at twenty minutes.) Thus the majority had no evidence of dysfunction. The liver edge was palpable and tender in 25 of these patients, the meaning of which remains obscure.

LIVER FUNCTION TESTS

Data contained in the records from overseas hospitals gave clear evidence that each of these patients had suffered with jaundice of varying magnitude and that this was related to the previous administration of yellow fever vaccine. Frequent icterus index and serum bilirubin determinations were made, and oral hippuric acid liver function tests were done. The results of these tests overseas indicated that, at some time during their hospitalization but many months after their acute illness, 125 patients had evidence of disturbed liver function (icterus index 20 to 40, quantitative van den Bergh determinations 1 to 3 mg.). In addition, the clinical histories indicated an uninterrupted chronicle of illness following the initial acute episode.

After the arrival of these patients at the Lovell General Hospital, tests of liver function were repeated (table 1). It was found that some patients still retained elevation of serum bilirubin (9 cases), palpable, tender liver edges (40 cases), and little or no evidence of subjective clinical improvement. Oral hippuric acid liver function tests done at this hospital gave uniformly negative results, which are in keeping with the lack of sensitivity of this test.

TABLE 1.—*Liver Tests*

Test	Overseas	Lovell General Hospital
Oral hippuric acid test abnormal * in...	20 (10%)	0
Icterus index abnormal † in.....	200 (100%)	9 (4.5%)
Sulfobromophthalein excretion abnormal ‡ in	.....	14 (12%)
Liver edge palpable in.....	.....	40 (20%)

* Three Gm. or over is considered normal.
† Indexes greater than 8 are considered abnormal.
‡ Any retention at the end of thirty minutes is considered abnormal.

In addition, it was found expedient to employ the serial sulfobromophthalein test for this entire group of 125 as laboratory evidence of disturbed hepatocellular function (chart 1). The amount of dye administered was 2 mg. per kilogram, and results showed that at the end of twenty minutes 40 patients retained more than 10 per cent of the dye and at the end of thirty minutes 14 patients still showed retention up to 15 per cent (chart 2). It was agreed that the thirty minute determination would be the laboratory criterion for evidence of disturbed liver function, giving an incidence of 12 per cent for the entire group tested by this method.

The following case reports are typical of the group considered to have hepatic damage:

CASE 1.—F. S., a private aged 26, became jaundiced four months after receiving yellow fever vaccine. Although he was jaundiced and voiding "dark urine" he continued on duty for twenty-seven days and was then hospitalized. A diagnosis of "catarrhal jaundice" was made. He was transferred to a convalescent hospital four days later where many such cases were treated, but his progress was discouragingly slow. When after four months he was still unable to do duty because of extreme fatigability and epigastric distress after meals, he was ordered back to the United States. His past medical and family

histories were noncontributory. Physical examination on admission to Lovell General Hospital was negative except that he was pale and complained of vague epigastric tenderness and weakness. The liver edge was palpable 1 fingerbreadth below the costal margin and was tender to pressure. The spleen was not palpable.

The pertinent laboratory findings are given in table 2. Additional studies, including barium meal with particular attention to the small bowel pattern, gastric analysis and oral cholecystogram, revealed no evidence of disease. The psychiatric consultant thought a mild psychogenic component was present.

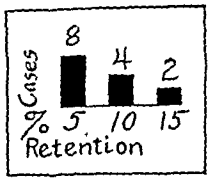

Chart 1.—Serial sulfobromophthalein tests, twenty minutes' retention.

In view of the soldier's history and his laboratory findings, it was the opinion that he had evidence of some degree of residual hepatocellular dysfunction ten months after his original illness and that a diagnosis of chronic hepatitis was inescapable.

A feature of interest in this case, and one seen not infrequently in the group, was the relatively high normal serum bilirubin on admission to our hospital and the subsequent return of subclinical and clinical jaundice. The exact significance of this was a matter of conjecture, although it would appear that the liver parenchyma was quite sensitive to relatively minor environmental changes. For example, a rise in the icterus index was noticed in several soldiers who had been allowed home on furlough, during which time they had indulged in alcoholic beverages. It was thought that in these instances the elevation of the serum bilirubin was directly related to this overindulgence. Incidentally, alcohol in any form was badly tolerated by these men.

Further, if one could use this patient's icterus index, serum bilirubin and sulfobromophthalein determinations as criteria of progress, one would be reasonably safe in concluding that there had been no improvement in liver function during his stay at Lovell General Hospital. However, this did not hold true for the majority of the group, in that the general trend of the laboratory findings was toward improvement.

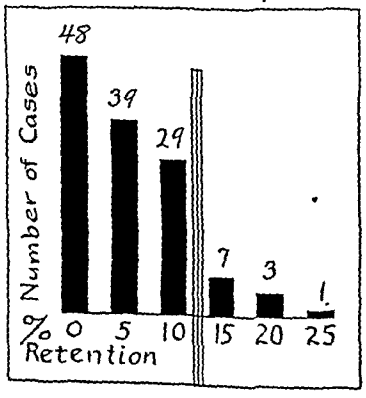

Chart 2.—Serial sulfobromophthalein tests, thirty minutes' retention in 125 cases.

CASE 2.—J. B., a young private, had received yellow fever vaccine on May 14, 1942 and was hospitalized because of anorexia, weakness and jaundice on July 14. His past medical history was negative except for "stomach trouble" described as low abdominal cramps, nausea and vomiting following the eating of foods as cheese, bananas and tomatoes. There was no history of allergy.

A diagnosis of acute hepatitis was made overseas. His acute course did not appear especially severe, but his convalescence was disappointingly slow, because of persistent anorexia, extreme fatigability and weakness.

On admission to Lovell General Hospital he was pale and thin, and he complained of fatigue, weakness, inability to digest "fatty foods" and anorexia. The physical examination was unimpressive. The liver edge was at the costal margin. His laboratory studies were all within normal limits except for the sulfobromophthalein determinations, which are given in table 3.

Additional studies, including cholecystogram, barium meal, stool studies and gastroscopy, failed to reveal evidence of organic disease.

It was the opinion that this soldier's acute hepatitis had resulted in some degree of hepatic dysfunction as evidenced by a rather pronounced degree of sulfobromophthalein retention. The essentially normal serum bilirubin in face of this retention was an interesting feature. Subjectively the clinical picture remained unaltered.

May 11, 1943	Single specimen 20% at 27 minutes		

It must be noted that in many instances there was poor correlation between liver function tests and clinical findings. Subjective manifestations were usually out of all proportion to laboratory evidence of liver involvement. Clinical improvement in some did not follow improvement in liver function tests, nor did completely normal tests always indicate a healthy person. On the other hand, there were some soldiers who were returned to full duty in good health still showing abnormal sulfobromophthalein retention.

NEUROPSYCHIATRIC SURVEY

The psychiatrist investigated 135 patients. A positive diagnosis of psychoneurosis was made in 115 cases, and in 4 others a diagnosis of probable psychoneurosis was justified, although the evidence was not so complete. Analysis of 103 of these neuroses revealed that 37 had a typical anxiety state and 66 had a mixed type of psychoneurosis.

TREMOR SYNDROME

The 37 patients included in group D presented clinical features of extraordinary interest. While it is true that vasomotor disturbances of varying magnitude are known to be associated with liver disease, the degree of imbalance was excessive in these soldiers. Reference has been made to the icy, red, wet extremities and to the constant pronounced tremor so intensified by muscular effort. Of even greater interest was the devastating and overwhelming weakness so apparent in all of these patients. For example, it was impossible for many to complete the writing of a postcard without resting at least once, nor could they dress themselves without noticeable exhaustion.

In an attempt to evaluate this weakness, 20 members of this group were studied in the Fatigue Laboratory at Harvard University. Here they were subjected to the "pack test," in which the subject is made to mount a 20 inch step at a certain cadence until he becomes exhausted or for a maximum of five minutes. A formula which takes cognizance of the duration of exercise and the rate at which the pulse returns to normal gives an index of physical efficiency. It was found by this test (table 4) that these patients turned in the lowest score of any group ever tested. Their

TABLE 4.—*Test for Physical Fitness*

B. Subject steps up and down 20 inch step, 30 round trips per minute
C. Index of physical efficiency,

$$I = \frac{\text{Duration of exercise in seconds} \times 100}{2 \times \text{sum pulses } ([1'\text{-}1\tfrac{1}{2}'] + [2'\text{-}2\tfrac{1}{2}'] + [3'\text{-}3\tfrac{1}{2}'])}$$

D. Average scores

Athletes	95
Normal unselected males	61
Men with neurocirculatory asthenia	30
Hepatitis	15

average score was 15, while that of soldiers with neurocirculatory asthenia was 30, of normal unselected males 61 and of athletes 95. These results corroborated the patients' statements that they were unable to exert themselves to any appreciable degree.

It is also of note that there was a masklike facial expression in 20 patients not unlike that seen in parkinsonism. There was, in addition, lack of free swing of the arms in walking.

Under a reconditioning program but little improvement could be noted in this group, as contrasted with the decided improvement in group A. They failed to gain in weight, and sweating of the extremities was still excessive. Tremor remained constant.

There was, however, objective evidence of improving liver function, and at the termination of these observations 23 patients (63 per cent) had fully recovered in this respect. Palpable, tender liver margins, varying considerably from day to day, were still noted in 20 patients (54 per cent). Biopsy specimens in 2 of these patients revealed normal liver tissue.

LIVER TESTS

The greatest caution must be exercised in arriving at final decisions where disturbed liver function is concerned. The organ has such varied functions that no laboratory test, done singly or in multiples, may be relied on implicitly to proclaim its state of disturbance. Attention has been directed to the impossibility of correlating the subjective complaints of these patients, the liver function tests and the size of the liver. This was manifest throughout the studies. It was not unusual for patients to return to full army duties clinically recovered but with adverse results of the last serial sulfobromophthalein tests. The reverse also was seen. Experience has indicated that this is not unusual in individuals who have suffered liver insult. Such organs also seem to react to subsequent somatic disturbances or even mild infections by mild or moderate relapses a long time after the original illness. It is of interest that, in a few of those patients who had recovered from early attacks of postvaccinal hepatitis and who came to autopsy after death from other causes, entirely normal livers were found. Likewise, biopsies performed on 2 of our patients revealed normal appearing but enlarged livers with histologically sound tissue. The importance of the evidences of liver dysfunction which our tests have revealed cannot be properly evaluated until the same tests are applied to a group of individuals who have had hepatitis and who are without any significant symptoms. It has been shown by Kornberg [1] and others that impairment in excretory function of the liver was present in a significant percentage of medical students who considered themselves in good health. That there are parenchymal and stromal lesions in the acute stage of epidemic hepatitis, which the disease in question so closely resembles, has been ably demonstrated by Dible and his associates [2] in a series of punch liver biopsies on patients so affected.

Abdominal Pain.—Mention has been made of pain in the right upper quadrant, elicited so often by exercise or by eating. Frequently it was almost a trigger response similar to angina pectoris. Sudden in appearance and severe enough to cause the patient to double up, the distress subsided in like manner after resting in the one case or vomiting in the other. This observation was verified at the Fatigue Laboratory during tests for physical fitness. Examination during such attacks revealed a tender liver edge but not one that had materially altered in size incident to effort. Whether peripheral blood counts done before and after these episodes might show change in cell counts would be an interesting point for investigation.

Gastrointestinal Symptoms.—The various digestive complaints were similarly difficult to evaluate. In many the symptoms arose almost immediately after taking the first bite of food or very shortly thereafter, and in either case too soon for any digestive action to have started. In others, nausea, distention, eructation and vague abdominal distress appeared from half an hour to one hour after eating small amounts of food. The patients cited so-called "fatty foods" as the prime offenders, but at the same time there was no intelligent appreciation of what comprised fatty foods. Meats, fried or otherwise, seemed to cause the most trouble, while butter, cream and even eggs apparently were well tolerated. Moreover, gastrointestinal x-ray studies on 60 patients and gastroscopies performed on 27 patients failed to disclose any pertinent findings. Then too, only a few of the arch sufferers retained any laboratory evidence of hepatic dysfunction, so that the clinical picture and laboratory findings were largely unrelated or

at least difficult or impossible to correlate. One is led to believe, therefore, that there is a strong neurotic aspect to these complaints.

PSYCHIATRIC FINDINGS

Of interest were the findings of the psychiatrists in their investigations of these patients. The final opinion handed down was that, for the most part, the individuals were disabled by a neurosis which had been latent but was rekindled and made manifest by an organic physical illness, in this instance hepatitis with jaundice. Aside from the gastrointestinal symptoms, it was felt that the total picture might well be that of increased tension, so frequently seen in a true neurosis, as a direct manifestation of anxiety. The gastrointestinal symptoms were considered continuations of those of the acute illness unconsciously prolonged as an escape from a difficult situation. In group A, and in a few other instances, the prolonged period of hospitalization, overseas service and concern by many physicians were thought to be adverse factors, since it is doubtless true that psychologic disturbances become more and more prominent in hospital wards.

TREATMENT

The vast majority of these patients were not in need of any specific type of therapy. However, the regimen which was finally adopted had as its goal (1) restoration of an adequate diet, with special attention to protein, carbohydrate and vitamin B complex requirements and (2) reconditioning and indoctrination.

Briefly, a very large number of these soldiers had to be instructed in the essentials of dietetics. Their prolonged illness and residence in hospitals and the continual discussions regarding their "interesting" disease were instrumental in creating vagaries about foods and indifference as to eating. In addition, actual aversion to the odors and first tastes of food had helped reduce consumption of necessary foods to a point where many were undernourished. With the eventual resumption of adequate diets, notable general improvement was noted. Clinical evidence of avitaminosis was not apparent, but the vitamin B complex was added in every case.

The most striking benefits were obtained from a carefully planned program of rehabilitation in which the patients were put into uniform, became once again part of the armed forces and spent a portion of each day at the sports arena indulging in graduated games and calisthenics. Movies and lectures designed to direct and educate these soldiers in the ideals for which they were fighting were also most helpful.

By adopting these simple methods, only 87 of the entire group (34 per cent) were eventually discharged from the service, and over half of these were released because of neurotic disorders which had existed prior to enlistment. Very little subjective improvement was noted in the group manifesting the tremor syndrome.

COMMENT

The actual number of soldiers who were originally vaccinated against yellow fever and who sustained liver inflammation is not stated for obvious reasons. It is of importance only as abundant evidence that the vast majority of those affected recovered quite promptly and, in all probability, completely. Likewise there are other features which stand out prominently. Complete restoration of function in a diseased liver may require a considerable time—for some, as long as six months to a year or even longer. That restoration does occur eventually has been observed in most of these soldiers. One must conclude that 12 per cent of the entire group still have some evidence of liver disease, as evidenced by the laboratory finding of some dye retention at the end of thirty minutes. This is a small number but interesting at this distance from the initial disease.

The tremor syndrome, so called, remains a noteworthy observation. Whether the entire picture will eventually subside, only time will tell. The question has been raised whether this symptom complex has arisen as the result solely of antecedent liver disturbance or largely anxiety neurosis. That the syndrome itself constitutes a real disability cannot be gainsaid. Fortunately, only 15 per cent of the study group fell into this category—a very small number.

CONCLUSIONS

1. A study was made of 200 patients with prolonged convalescence after postvaccinal (yellow fever) hepatitis.

2. Only a small number of those soldiers originally suffering from postvaccinal hepatitis sustained prolonged disabling illness.

3. Psychoneurotic patterns may develop as a complication of this illness. Antecedent patterns may be reborn.

4. The sulfobromophthalein test for liver function in 125 cases showed that at the end of twenty minutes 40 patients (32 per cent) had some dye retention and that at the end of thirty minutes 14 patients (11 per cent) showed some dye retention. None of the other patients had objective evidence of liver dysfunction.

5. Improvement in damaged liver function is still continuing at the end of six months to a year.

6. Correlation of symptoms, laboratory tests and incidence of palpable liver edges were not possible in most cases.

7. Thirty-seven patients (18.5 per cent) have a vasomotor disorder manifested by pronounced tremor, icy cold, red, dripping hands and overpowering weakness.

ABSTRACT OF DISCUSSION

DR. JOSEPH STOKES JR., Philadelphia: Our studies began in June 1942, when a pool of convalescent mumps plasma from a large army post, plasma which we used in 1 case for experimental treatment of mumps, produced jaundice in this man seventy-five days after his infection. This pool of plasma has been used since that time for the intravenous injection of 5 additional men, volunteers, and has produced hepatitis in all of them, with overt jaundice in 4. Plasma was obtained from 1 of these 5 men at or near the start of his hepatitis at twenty-three days from the time that he had been inoculated with the original pool of plasma, and this plasma was injected into 2 additional volunteers. Both of these volunteers also developed hepatitis. In 2 other volunteers we injected subcutaneously yellow fever vaccine which had been produced for the Army in November 1942. It was kept in the cold until January 1942 and then at room temperature, including two summers in Washington, from June 1942 to November 1943. The yellow fever virus by this time was shown to be inactive, but the agent causing hepatitis was demonstrated as still active, since it produced the hepatitis in both of these volunteers injected. Of the 10 men, therefore, whom I have mentioned, hepatitis was produced in all by these various materials. Approximately eighteen liver function tests were used. The most valuable tests were

the serum and the urine bilirubin, the sulfobromophthalein test, cephalin, the cholesterol flocculation test and the vitamin A level in the blood. The vitamin A level is not specific but when correlated with the other tests was of considerable assistance. The incubation period in this group was from twelve to thirty-five days. Acute symptoms of gastrointestinal disturbance appeared first. At that time the liver function tests were abnormal. There was then usually a period free of symptoms in which the liver function test still indicated hepatitis. Finally, in most instances in between 75 and 110 days overt jaundice appeared. One of the men has been reinoculated with the same pool of plasma obtained from the army post one month after his liver function tests were normal and it is now well over a hundred days and he has not shown any evidence of hepatitis by the liver function studies or any jaundice. Laparotomy was performed in 1 of the cases during the height of the intestinal symptoms, and in that instance enlarged mesenteric glands were found with a regional or localized ileitis which is evidence of the generalized infection. Whether serum jaundice and infective hepatitis or infectious hepatitis of an epidemic nature are similar or different is still a question for discussion. The fact that we found early evidence of hepatitis by liver function studies thirty days after inoculation suggests that there may be greater similarity than at first had been supposed.

LIEUTENANT COLONEL JOSEPH BANK, El Paso, Texas: Colonel Benjamin and Colonel Turner and other investigators who have studied jaundice following yellow fever vaccine have caused us to scrutinize postvaccinal convalescents for residual or recurring symptoms. As a result we discovered many patients in whom symptoms recurred after return to duty following recovery. In addition we found other cases of hepatitis not associated with yellow fever vaccine but with similar findings. The latter patients can be divided into two groups. The first and larger consisted of those with deep jaundice, whose condition was diagnosed immediately and who were hospitalized. The second, smaller, group includes those with slight or unrecognized jaundice and with fatigue and vague gastrointestinal symptoms. A typical case may be a soldier who may or may not be aware of a mild attack of jaundice a long time before. Some months later he may complain of gastrointestinal symptoms and fatigue. Examination reveals little jaundice or an icterus index within the upper limits of normal, enlarged tender liver and particularly decreased sulfobromophthalein excretion by the liver. The test we used was the 5 milligram dose with determinations at thirty and forty-five minutes. One other point I should like to make about the acute cases: We have seen to date about 6 patients who were operated on for suspected abdominal emergencies but with negative findings. Several days later they developed jaundice and the usual picture of acute hepatitis.

COLONEL JULIEN E. BENJAMIN, M. C., A. U. S.: The groundwork for the recognition of this syndrome really started with the air forces when a large number of these cases were received. I should like to emphasize the fact that there were these fairly large numbers of troops who were invalided with a vague syndrome; that the only proof that we have of any organ that might be responsible is that of the liver, and we haven't really abundant proof because of the notorious fallibility of liver tests. Still it seems inescapable in the light of the clinical picture of these individuals that residuals of hepatitis were present.

Sleep During Middle Period of Life.—The interruption of rest by local disease, occurring to persons in the middle period of life, does not cause the same degree of exhaustion and wasting as in the young. They bear the loss of sleep better, because their constitution has to sustain the stress of repair only—not of both development and repair, as in the child. Their recovery is slower; their subsequent sleep is not so profound nor so prolonged, nor their rest so complete. The defective sleep and slow repair which manifest themselves in the old after injury of any kind are familiar to us all.—Hilton, John: Rest and Pain, London, George Bell & Sons, 1857.

INCIDENCE OF RAT BITES AND RAT BITE FEVER IN BALTIMORE

CURT P. RICHTER, PH.D.
BALTIMORE

Wild rats, even more than any domesticated animals, enjoy very intimate living arrangements with man. They can live in the same house, share the same beds, eat the same foods, carry the same internal and external parasites, suffer from the same diseases and plagues. Man has made numerous unsuccessful efforts to terminate this close relationship and has at all times manifested a great distaste for any physical contact with these companions, either dead or alive. Rats on the other hand are less discriminating, even seeking contact with man and treating him much as they do the dying or dead members of their own species—running over him, licking him, biting him and finally trying to eat him.

The latter aspect of the rat's relationship to man has not received much serious attention. This paper, therefore, deals with the frequency with which rats bite man, the circumstances under which they bite him, their motive in biting him, and finally the results produced in man by their bites.

Parts of Body Bitten by Rats

	Number of Persons with Bites
Arms	
Hands and fingers	41
Forearm	5
Shoulder	2
Head	
Cheek, lips	11
	5
	4
Legs	
Feet	19

The data on which the present report is based came from the Pediatric Dispensary and the Accident and Medical Departments of the Johns Hopkins Hospital, from the follow-up of these cases by several workers and from voluntary reports made by citizens to the Health Department and Rat Control Office of the city of Baltimore. In the hospital, data were available only for the four year period from 1939 to 1943. Since that time records on rat bites in the Pediatric Dispensary and the Accident Departments have been discontinued because of the war.

During this four year period 87 persons were treated for rat bites or the results of rat bites in the Johns Hopkins Hospital. Sixty-five of these persons, or 75 per cent, came from an area of less than 2 square miles surrounding the hospital. The follow-up of 43 of the cases in this area yielded records of 12 more persons having been bitten by rats. Sixteen of 51 bitten persons who during this period were voluntarily reported to the health department came from this same area. Thus a minimum of 93 persons were bitten during

From the Psychobiological Laboratory, Phipps Psychiatric Clinic, Johns Hopkins Hospital.

The work described in this paper was done under a contract, recommended by the Committee on Medical Research, between the Office of Scientific Research and Development and the Johns Hopkins University.

Dr. Mary Goodwin, who was in charge of the Harriet Lane Dispensary, provided the names of patients treated in the dispensary; Dr. Huntington Williams, Commissioner of Health, gave us the names of citizens who had voluntarily reported rat bites to the health department. The follow-up work was done by Mrs. Joseph Leach of the Woman's Civic League and Mr. N. Wolbarsht.

a four year period, or 23.2 per year, in an area of this than 2 square miles. A house to house canvass of this area would undoubtedly have provided many more instances, since in these heavily rat infested districts most people apparently accepted rat bites as being inevitable. They came to the hospital for treatment only when the bites had become infected or the skin had actually been torn or chewed away. The fact that rat bites are not reportable to the health department also means that many persons may have been treated by their family physicians and so would not have been included in the records either of the hospital or of the health department.

Most of the rat bites occurred in a part of the Eastern Health District which has very poor housing and living conditions and is inhabited largely by colored people. In the block map of the Eastern Health District shown in figure 1 it can be seen that almost all of the rat bites (solid dots) were located in blocks with a high percentage of colored people (indicated by cross hatching). In the eastern part of the Eastern Health District, which has good housing and living conditions and is inhabited largely by white people, only a few persons were bitten. It does not follow that the rats bite only colored people. Actually only 58 of 93 bitten persons, or 62 per cent, were colored.

Of the 65 persons from the 2 square mile area that were treated in the Johns Hopkins Hospital and on whom we have full records 7, or 10.7 per cent, developed rat bite fever. None died and none developed any other rat borne disease.

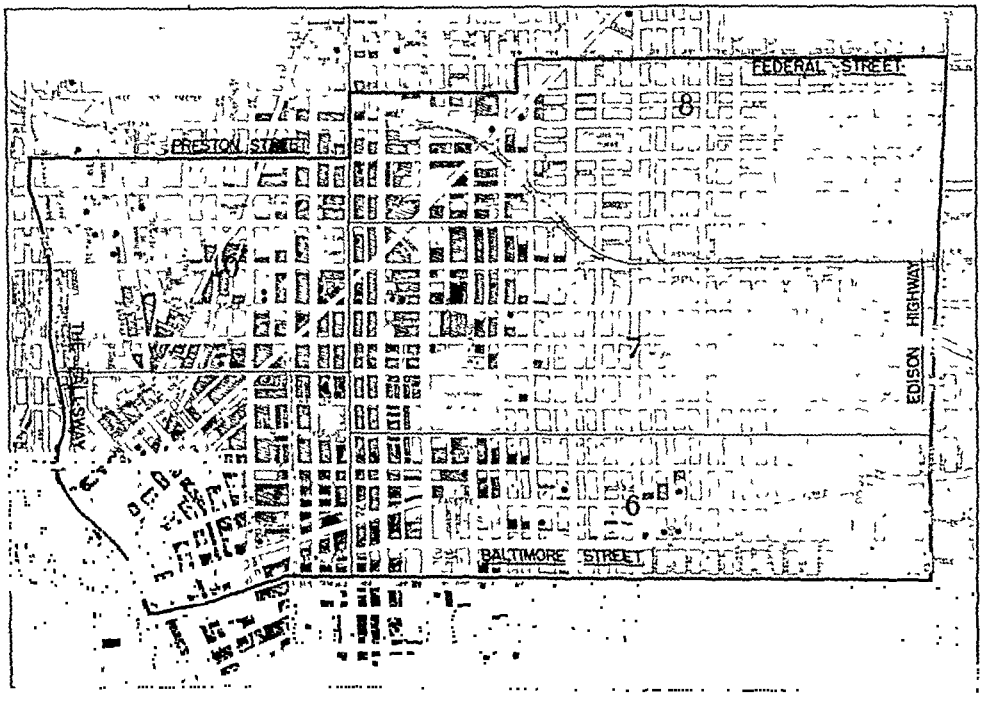

Fig. 1.—Map of Eastern Health District (heavy black line) showing colored population (cross hatching) and location of persons who were bitten by rats (black dots). The Johns Hopkins Hospital is located almost in the center of this district.

The study of these data gives other information of general and medical interest. It was found that although the ages of the bitten persons ranged from 2 months to 65 years, the great majority were infants under 1 year of age. Figure 2 shows the age incidence curve for the 87 persons treated in the hospital. Especially noteworthy is the fact that without exception all of the persons on whom we have records were bitten at night, presumably while asleep. There were no records of persons having been attacked by rats while awake.

In the 87 hospital treated patients the parts of the body most favored by the rats were the fingers and hands, as may be seen in the accompanying table.

Thus, as would be expected since the rats did the biting only while the victims were asleep, the uncovered parts of the body, namely the hands and the face, were bitten most frequently.

Twenty-five persons received multiple bites on the same or different occasions. One child was bitten on eleven different nights. Thirty-nine of the 93 patients came from one house or the immediately adjoining houses. Since these houses were not more heavily infested than many others, we may draw the conclusion that once a rat has bitten one human being it is apt to return again. In one house 4 children and 2 adults were bitten within a short time.

A strong craving for blood might explain why once having bitten a person the rats apparently are apt to bite another person. In order to determine whether rats like fresh blood, we offered them human blood obtained from the hospital operating room. The 8 rats used for these observations had recently been trapped in the city alleys and yards. At 11 a. m. each of 5 rats were given 50 cc. of fresh blood mixed with 8 per cent citrate and were given free access to dog chow and water. By 9 o'clock on the following morning 2 rats had eaten 50 cc., while 3 had eaten 20, 10 and 8 cc. respectively. At 11 a. m. each of the 3 other rats were given 139 Gm. of fresh blood and serum with access to water but not to any other food. By 9 o'clock on the following morning 2 of the rats had eaten all of the blood and 1 had eaten 47 Gm. When one considers that the average normal food intake of full grown wild rats does not usually exceed 35 to 40 Gm., the large intake of 139 Gm. indicates that the rats had a real craving for this fresh human blood.

COMMENT

The results of this sampling study indicate that a large number of persons are bitten by rats each year. It is probable that if so many are actually bitten a far larger number must have direct physical contact with rats, that is, rats run over them, lick them, and so on. In densely populated and rat infested areas the rat bites and this direct physical contact may thus constitute a hitherto overlooked means of transmission of such diseases as poliomyelitis and rabies.

It was reported that in all instances the persons were bitten at night while asleep, not while they were defending themselves. It may be asked then why the rats

bite the sleeping persons. Observations which we have made on the behavior of wild rats may answer this question. We have observed repeatedly that wild rats eat dying or dead rats with great relish. They start at the head and work down and often devour the entire body, hair, bones and even teeth. They often prefer dead rats to other foods. It is likely therefore that the rat regards the human being, particularly the blood, also as food. After exploring the quiet sleeping person the rat probably starts to eat and if not stopped at once continues to eat. Rats have been known to eat most of the cheeks and noses of babies before being driven off. Brehm [1] reports that in zoos they have been known to eat and gnaw away at the feet of elephants, in 3 instances in the Hagenbeck Zoo near Hamburg causing the death of the animals. He reports further that on farms rats have been known to eat the webs between the toes of ducks, to eat holes in the bellies of fat pigs, and near a slaughterhouse to devour 35 dead horses in one night.

It is very likely that the rats involved in the present observations belong exclusively to the common Norway species (Rattus norvegicus), which has omnivorus food habits. This statement is based on the finding that except along the water front only Norway rats were caught or recovered in an extensive trapping and

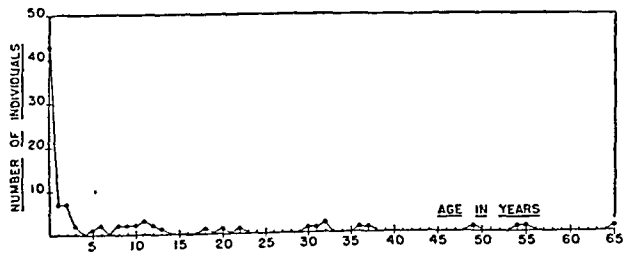

Fig. 2.—Age incidence curve for the 87 persons who were treated at the Johns Hopkins Hospital for rat bites.

poisoning campaign. It is possible that the herbivorus Alexandrine (Rattus alexandrinus) may not bite human beings with the same frequency if at all. Further observations in cities inhabited largely by the Alexandrine rats should answer this question.

SUMMARY

1. Within an area of less than 2 square miles in the city of Baltimore a minimum of 93 persons were bitten by rats during the four year period from 1939 to 1943.

2. Of these persons 65 received treatment at the Johns Hopkins Hospital, which is located within the 2 square mile area.

3. Of this number 7, or 10.7 per cent, developed rat bite fever. None died.

4. The age of the patients ranged from 2 months to 65 years. Sixty per cent were babies under 1 year of age.

5. The patients were bitten while asleep. The hands and face, which are exposed during sleep, were most frequently bitten. In many instances the bites did little more than puncture the skin and draw blood before the patients were awakened; in some cases, however, part of the face was chewed away.

6. The evidence indicates that once having bitten a human being the rats are apt to bite other human beings.

7. It was concluded that the rat regards the sleeping infant or adult as a source of food. In most instances the first bite awakens the victim, frightens the rat away and thus interrupts the meal.

8. Persons are much more apt to be bitten in heavily infested districts with poor housing and living conditions.

9. The high incidences of rat bites and the probably much higher incidence of actual physical contact between the rats and human beings may indicate that physical contact constitutes an overlooked channel for the transmission of diseases from rats to human beings.

ABDOMINAL PAIN DUE TO UROLOGIC DISEASE IN CHILDREN

MEREDITH F. CAMPBELL, M.D.
NEW YORK

In patients with symptoms of intra-abdominal disease the difficulties of precise anatomic diagnosis are often greatly increased by clinical manifestations due to a wide variety of extra-abdominal lesions. Hematologic, allergic, orthopedic, respiratory, endocrinologic, infectious or urologic disease frequently leads to erroneous diagnosis and mistaken surgical intervention. The diagnostic problem is usually difficult enough in adults but is notoriously more difficult in children, and in the very young the clinical approach must be largely objective. It is recognized that in infants and children with symptoms of acute abdominal surgical disease laparotomy is often the urgent indication even though the differential diagnosis may be in doubt. Only by this method will the mortality of acute appendicitis, for example, be reduced.

Abdominal pain commonly results from a localized intraperitoneal disease, as appendicitis, cholecystitis or diverticulitis, or is widespread, as in general peritonitis. The abdominal projection of pain through the vagus from an acute infection of the upper respiratory tract is well known. The sudden distention of a hollow viscus is one of the most frequent causes of abdominal pain and may vary from the intestinal gas bubble, which produces colic in the infant, to severe intestinal obstruction and distention by angulation, bands or intussusception. Except for the colic of infancy, children rarely suffer pain, nor is indigestion or constipation likely to cause it in the young. Most acute abdominal pains in children demand surgical consideration and frequently laparotomy. Moreover, it is recognized that abdominal exploration had best be performed in many children presenting this clinical picture than that a fatality should result from failure to recognize the emergency condition. Rather we are chiefly concerned here with the persistent or recurrent abdominal pain in children whose condition does not demand emergency surgical treatment and in whom a comprehensive examination, including urologic investigation, should be car-

From the Department of Urology, New York University College of Medicine.

Read in a symposium on "Abdominal Pain in Children" before the Section on Pediatrics at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 15, 1944.

ried out before subjecting the patient to exploratory laparotomy. In many children of this group the abdominal pain will be demonstrated to have resulted from either gradual or rapid distention of the collecting part of the urinary tract above an obstruction, which in turn may be located at any point from the external urethral meatus to the renal calix. The advent of infection usually intensifies the clinical manifestations including pain and materially adds to the gravity of the prognosis and therapeutic problem.

As an unfortunate corollary, clinicians commonly fail to recognize that in half of all patients with advanced obstructive uropathy, and particularly with complicating infection, symptoms of chronic gastrointestinal disease are prominent and may overshadow other subjective symptoms of urinary tract disease. As a result the erroneous diagnosis of biliousness, intestinal indigestion, dyspepsia, chronic appendicitis, gallbladder disease and so forth is too often made. This is true in patients of all ages but is particularly notable in the young. The success of the indicated urologic treatment, often surgical, attests the fundamental correctness of the diagnosis.

With ureteral obstruction the pain of the resulting pelvorenal distention is likely to be most pronounced in the lateral and posterior loin. Yet commonly this pain is referred to the isolateral lower abdominal quadrant or even to the midabdomen. The chief potential causes of urologic abdominal pain are the obstructive lesions of the urinary tract; the large variety are indicated in the accompanying table, in which hydronephrosis, ureteral stricture, ureteral obstruction by aberrant vascular compression and obstructions at the bladder outlet or in the deep urethra are of highest incidence.

Persistent pain or swelling along the course of the urinary tract urgently demands a complete urologic examination. Urinalysis is a diagnostic requisite and, in the female, the specimen should always be collected by catheterization. Urinalysis, thorough physical examination and a satisfactory excretory urographic study represent the minimum of urologic investigation and will often leave the diagnosis in doubt. When the excretory urogram does not readily suggest the anatomic diagnosis, cystoscopy, ureteral catheterization and retrograde pyelography are necessary. When obstruction, usually stricture, involves the body of the right ureter the clinical diagnosis is usually chronic appendicitis, as I have now observed in 29 children. In 15 instances the appendix had previously been removed and in some was frankly reported as normal. In the others it was identified as "chronic," which may or may not have been a gratuity of the pathologist. The important consideration in these cases is that the original pain persisted and again brought the child to the hospital. It is now recognized in most teaching hospitals in this country that laparotomy for so-called chronic appendicitis should be delayed until disease of the urinary tract has been excluded. In short, one should perform adequate urologic investigation on any patient before subjecting him to an abdominal operation for "chronic appendicitis" or "abdominal adhesions."

An acutely inflamed appendix overlying the ureter may cause the appearance of red blood cells and leukocytes in the urine, but even here, and especially if there is question as to the diagnosis, one should perform an excretory urographic study, which will not consume more than twenty minutes and may be expected to be of diagnostic clarity in at least half of the children for whom it is employed. In 3 young patients the "acute appendicitis" proved to be right ureteral stone.

Lower abdominal pain commonly results from vesical urinary retention; an estimation of the residual urine should be made.

It cannot be overemphasized that a normal urine does not rule out grave urologic disease.

Approximately 1 in 8 of all children are born with some type of urogenital tract anomaly, and urinary obstruction can be demonstrated in about a fourth of these. Stricture of the ureter is one of the commonest congenital obstructive lesions, and in a series of 12,080 autopsies on children that I reported, congenital ureteral obstruction, chiefly stricture, existed in 95 (1:138). Yet all urinary tract anomalies are potential causes of urinary stasis. The blockage may be (1) intrinsic, as in stricture of the ureter, congenital contracture of the bladder outlet or stenosis of the external urethral meatus, or (2) extrinsic, as by extraureteral compression by an aberrant vessel, or (3) an abnormality in the course of the ureter may interfere with urinary drainage, as in horseshoe kidney disease or other forms of renal fusion or ectopia

Chief Potential Causes of Urologic Abdominal Pain

The clinical background of this discussion is the personal complete examination of 319 children admitted to the hospital and in whom abdominal pain was the chief complaint or was an outstanding symptom. Acute or subacute urinary infection was suspected from the first in half of these or was discovered after an early examination of the child. Yet in 26 instances appendicitis was the original diagnosis, usually designated as "chronic," and in 17 other children of this series appendectomy had been previously performed for symptoms which, persisting after operation, again brought the child to the hospital. In some children the cause of the pain continued to remain obscure despite extensive laboratory, gastrointestinal, surgical and urologic examinations.

In the following paragraphs the more important urologic lesions which may cause abdominal pain are briefly discussed and illustrative cases are cited.

RENAL LESIONS

Congenital Unilateral Aplasia of the Kidney.—This has occasionally been disclosed as the cause of abdominal pain in adults. In these cases distressing symptoms have promptly disappeared following removal of the diseased maldeveloped organ. I have encountered this condition but once in the young. This 7 year old child suffered mild abdominal pain but was examined primarily because of hypertension (240/140 mm. of mercury) and was known to have persistent pyuria. Removal of the diseased aplastic kidney reduced the pressure to 130/105, and the abdominal pain disappeared.

Abnormal Renal Mobility. — This seldom produces acute ureteropelvic angulation in children and the clinical picture of Dietl's crisis so often seen in adults. Nevertheless we have observed this syndrome in the young in whom the clinical picture was that of ureteral colic. The diagnosis is readily established by ureterography with the patient in the flat, Trendelenburg and upright positions and, as a rule, a renal supporting belt is adequate therapy. When this conservative measure fails, relief of the peripheral or local obstruction and nephropexy are demanded.

A 6 year old girl was admitted to the hospital with a diagnosis of abdominal tumor; this moderate size mass could be pushed into all quadrants of the abdomen except the left upper, was slightly tender and, at first, was thought to be a mesenteric cyst. Urologic examination disclosed it to be a congenital solitary right freely movable kidney on a long pedicle; a mild ureterovesical junction stricture of this ureter existed. A belt for renal support was adequate treatment.

Anomalies of Renal Fusion.—These are often manifested by pain, which may be due to urinary obstruction consequent to an irregular course of the ureter, unusual traction on the anomalous renal blood supply or complicating surgical disease, notably stone. A 12 year old girl was admitted to the hospital because of pain and tumor in the lower part of the abdomen. As she lay flat on her back a suprapubic protuberance simulating a distended bladder was readily visible and was proved to be a bilateral renal fusion in which both kidneys were joined in a gnarled mass overlying the sacrum and caused compression of the bladder. A lower abdominal supporting belt sufficiently elevated the fused organs to relieve the drag on the renal pedicle and thus relieve the pain of which this child complained. An 8 year old girl whose left kidney lay fused with the right in the right lumbar gutter had been subjected to appendectomy a month previously because of sharp pain in the right side; a normal appendix was removed. Subsequent urologic examination revealed a stricture at the vesical junction of the ureter which drained the right lower renal pelvis; instrumental dilation of this stricture cured the "appendicitis."

Horseshoe Kidney Disease.—Abdominal pain is a common symptom of this, particularly about the umbilicus. A 9 year old boy was operated on for acute appendicitis because of acute pain in the right loin and a temperature of 104.5 F. On entering the locale of the acute disease the operating surgeon penetrated a large cavity filled with purulent urine, inserted drains and backed out. The temperature rapidly returned to normal but the urine continued to drain from the wound for several weeks. The patient then came into my hands, and urologic examination revealed a pelvic horseshoe kidney the left half of which was located over the sacrum while the other half extended high into the right lower abdominal quadrant. A stricture at the right ureteropelvic junction produced hydronephrosis and, with acute ureteral obstruction and exacerbation of smoldering infection in the hydronephrotic kidney, fever and pain simulating appendicitis resulted. The diseased right half of the horseshoe kidney was resected, and the remaining half now excretes 70 per cent phenolsulfonphthalein in two hours and the urine is sterile.

Another clinical picture in horseshoe kidney disease is illustrated by the case of an 8 year old girl who for several months had suffered sharp pains in the right upper quadrant, leading her pediatrician to be sure she had gallbladder disease. In fact this fruitlessly had led to eight complete cholecystographic studies and three complete gastrointestinal roentgenographic investigations. An excretory urographic study was suggested, and this disclosed right hydronephrosis; completion of the urologic investigation with ureteral catheters and retrograde pyelography revealed a horseshoe kidney with congenital stricture of the right ureteropelvic junction and massive infected hydronephrosis. A less severe congenital stricture at the level of the fifth lumbar vertebra on the left side produced left hydronephrosis graded 1 plus. Resection of the horseshoe kidney with removal of the right half was highly successful; digestion at once improved, she gained weight rapidly and all abdominal symptoms disappeared. Subsequent periodic dilation of the left ureteral stricture completed the therapy.

URETERAL OBSTRUCTION

Stricture.—The frequency and potential gravity of congenital ureteral stricture has been indicated in preceding paragraphs. The surgical diagnostic difficulties this lesion may engender are illustrated by 2 cases: A 5 year old girl was admitted to the hospital with a diagnosis of recurrent subacute appendicitis during the past three years. The urine was normal, but an excretory urographic study fortunately was made before contemplated laparotomy. This revealed a stricture at the junction of the lower and middle third of the ureter on the right side, in other words just behind the appendix. Following periodic progressive dilation of the stricture with ureteral bougies, all symptoms of the "appendicitis" have now been absent for more than five years. In a 4 year old girl with the same symptoms on the left side and thought to have a left sided appendicitis, the clinical and therapeutic sequence has been the same. In both instances the child was spared laparotomy.

Vascular.—Obstruction of the upper ureter by aberrant renal vessels which pass from the lower pole of the kidney mesially to the aorta, to the vena cava or to the renal pedicle produce variable and often intermittent hydronephrosis, the pain of which is usually in the loin but is sometimes referred to the lower abdominal quadrant or to the umbilical area. Here urologic investigation is apt to be neglected unless there is persistent pyuria. Rarely aberrant uterine vessels block the lower end of the ureter. I have now seen 26 children with upper ureteral blockage by anomalous renal vessels and in whom persistent or intermittent abdominal pain was a prominent symptom. In some there was complicating persistent pyuria; in 7 appendectomy had previously, but fruitlessly, been performed to relieve pain. In

13 cases obstruction was eradicated by dividing the obstructing vessel, and in the other cases nephrectomy was required because of advanced renal injury.

Ureteral Kinks and Angulations.—These are seldom clinically important in children. I have encountered but 1 case in which operation seemed indicated. This 5 year old girl was admitted to the hospital because of persistent pain in her left loin and was thought to have surgical disease of the descending colon. Urologic examination revealed a fixed kink, probably congenital, in the upper third of the ureter; the kink persisted in urograms taken in the flat, upright and Trendelenburg positions. Surgical mobilization of the kink with nephropexy and subsequent periodic dilation of the ureteral stricture at the site of the kink were curative.

Diverticula.—A diverticulum of the lower left ureter in a 4 year old girl produced pain which caused the diagnosis of left sided "chronic appendicitis" to be made. The urogram readily suggested the anatomic diagnosis, and excision of the sac stopped the pain, which was due to ureteral compression by the distended diverticulum.

Calculus.—Because of improved dietetics in infancy and childhood, urinary calculus is seldom seen in the young in this country today. In most children with ureteral calculus the initial diagnosis of appendicitis or other intra-abdominal disease is usually made, but I have seen several in whom fortunate early urologic investigation averted needless laparotomy. Among these patients was a 4 year old boy admitted to the hospital with acute pain in the left loin radiating toward the testicle, with increased frequency of urination. Urography revealed a triangular calculus, approximately 7 mm. in diameter, in the upper third of the ureter. Therapeutic ureteral dilation was carried out, following which the stone was passed into the juxtavesical segment, where it was held up at the point of crossing of the vas deferens. Since it moved no farther downward during three weeks of observation, it was removed by ureterotomy. The stone was found firmly ennested and could progress no more, and the wisdom of open operation was confirmed. A 12 year old boy who ten days previously had undergone appendectomy for acute gangrenous appendicitis suddenly developed acute left abdominal pain with nausea and vomiting; there was considerable intestinal distention with shock, and it seemed likely that acute intestinal obstruction had developed. On one occasion during this postoperative complication pain had been referred to the left testicle, and there was some frequency of urination. An excretory urographic study was advised and performed. This disclosed a small shadow about the size of a grain of rice (8 by 3 mm.) in the midportion of the left ureter and two hours later this stone spontaneously passed, with prompt relief of all symptoms. Here the early employment of excretory urography caused the diagnosis of probable intraperitoneal disease to be ruled out and spared the boy the hazard and morbidity of laparotomy at a critical moment.

Vesical Distention.—Too often in children this condition, unrecognized, is the cause of low abdominal pain. Neuromuscular disease, congenital contracture of the vesical outlet, congenital hypertrophy of the verumontanum, congenital valvular obstruction of the prostatic urethra, congenital stricture of the urethra and congenital stenosis of the external urethral meatus are the commonest causes. In 2 instances hypertrophy of the verumontanum and congenital valvular obstruction coexisted. Yet in such cases the history of dysuria with frequency of urination should suggest a clue, particularly as so often there is complicating urinary infection with persistent pyuria. The diagnosis is readily made by cystourethroscopy and the obstruction removed by transurethral electroresection with miniature instruments. In some cases of chronic hypotonic vesical urinary retention I have found the administration of acetylcholine salts effective in stimulating bladder emptying.

Congenital Stricture of the Urethra.—This is frequently observed in children, while the traumatic and postgonorrheal varieties are rare. These lesions are apt to cause abdominal pain only when vesical overdistention results. In nearly every instance progressive periodic dilation with steel sounds is therapeutically effective. Of the lower urinary tract obstructions stricture at the external meatus is by far the commonest and may be of grave clinical importance. In a recent study of 152 cases of this variety, abdominal pain was found to be an outstanding symptom in 9 and was due to vesical distention. The diagnosis is made by inspection; wide meatotomy and the maintenance of a normal urethral caliber constitute the treatment.

Miscellaneous Conditions.—Palpation of the testicles is a most important part of the physical examination in males and particularly in those with symptoms of acute intra-abdominal disease. Torsion of an intra-abdominal testicle may suggest acute appendicitis or other serious lower abdominal surgical lesions. I have observed this in 1 boy with torsion of a right intra-abdominal testicle and in 3 others in whom the strangulated organ was at the internal inguinal ring. Moreover, torsion of the testicular appendix may cause differential diagnostic difficulties.

In rare instances malignant tumor of the kidney (embryonal adenomyosarcoma or Wilms tumor), new growths of the adrenal or of the lumbar sympathetic chain, and notably the neuroblastomas may cause abdominal pain in the young and remain unrecognized until the tumor mass is sufficiently well developed to be readily palpable.

COMMENT

The relatively high incidence of urologic conditions which may produce abdominal pain in infants and children has been indicated. Congenital ureteral obstructive lesions are common and, when right sided, are likely to cause the erroneous diagnosis of appendicitis to be made. No patient should be operated on for "chronic appendicitis" or "abdominal adhesions" until adequate investigation has ruled out urinary tract disease as a possible cause of the clinical manifestations. Because of the high mortality engendered by delay and neglect, most children with symptoms of acute intra-abdominal disease should be given the benefit of early laparotomy; but except in these cases urologic investigation and the correction of associated urologic disease may advisedly precede exploratory laparotomy, since the first procedure may render the second unnecessary. The urinalysis is usually abnormal in serious urinary tract disease, but the urine may be normal even though advanced obstructive uropathy exists.

ABDOMINAL PAIN IN CHILDREN FROM A SURGICAL STANDPOINT

ALFRED A. STRAUSS, M.D.
CHICAGO

There is probably nothing more perplexing or difficult to evaluate than abdominal pain in children, or to estimate the pathologic condition in the abdominal cavity in these cases. The young child himself is not old enough to talk, or, if he is, it is difficult to determine from his description how much pain he really has. In children up to 5 or 6 years of age it is hard at times to make out local tenderness or the local areas that are affected in the abdomen by percussion or palpation. Again, the physician or the surgeon is dependent on the intelligence of the mother, who has been with the child, for an accurate history of the course of the disease and the duration of the symptoms. In view of these two factors it is often difficult for the surgeon to decide whether he is dealing with a surgical condition in the abdomen.

Another factor is the many medical conditions that occur in children such as enteritis, enterocolitis, the eruptive exanthema and the cases of infantile paralysis which occur during the periodic epidemics. During the epidemic in Chicago in 1943 my associates and I were called on to operate in 4 cases of so-called acute appendicitis, but operation was not performed in these cases as the condition proved to be infantile paralysis.

CONDITIONS TO BE DIFFERENTIATED

Of the many conditions that can produce acute abdominal pain in children, the following are the most important to be considered in making a differential diagnosis:

Acute Enterocolitis.—Probably the most difficult differentiation is between acute suppurative appendicitis and acute enterocolitis with diarrhea in a child from 1 to 3 years of age. Many times the appendix is allowed to rupture because the child had diarrhea, and for this reason the pediatrician or the internist decided that the condition could not be appendicitis. From our past years of experience we feel that if there is the slightest doubt or question in cases of abdominal pain in children, operation should be performed. With careful induction of anesthesia and operative procedure we have never seen any bad results from such surgical intervention, even though operation may not reveal acute appendicitis or an acute condition in the abdomen. On the other hand, we have seen too many cases of critically ill children in whom, when operation was finally performed, a peritonitis was encountered from an overlooked gangrenous appendix which had ruptured. The mortality rate in neglected cases is much higher, and the children are many times critically ill from one to two weeks, while if operation had been carried out earlier they could be making a rapid recovery. Often the pediatrician or the internist hesitates to make a diagnosis of appendicitis if the patient's pain and tenderness is high up on the right side, in the region of the liver; but the pain is localized there owing to the fact that the cecum and appendix are still high up in the right side and have not yet rotated completely into the lower right side of the abdomen.

Intussusception.—This condition, which occurs usually in the first year of life, is characterized by symptoms of acute agonizing pain, which can subside; then complete relaxation of the abdomen followed by bloody mucous stools. However, intussusception is often overlooked because of an inaccurate history of the symptoms of the child from the mother, from poor observation or from the presence or absence of blood in the stools, which is dependent on the amount of strangulation of the mesentery. Many times the diagnosis is not made until the abdomen becomes distended and tense from a gangrenous intussuscepted bowel. There are many intussusceptions which are mild in character and in which there are no bloody stools present, and there are also recurrent intussusceptions that occur later in life, which are mild in character and do not produce bloody stools. These intussusceptions can exist for several days or weeks without damaging the colon, and they may be felt as a soft tumor in the abdomen, as I will describe later.

There is always a question between the surgeon and the pediatrician whether the intussusception is still present or whether it has released itself spontaneously. This, of course, can be determined with a roentgenographic examination with barium, for if the intussusception has reduced itself the barium passes readily into the ileum. This is true in about 95 per cent of the cases since the ileocecal valve is incompetent in infants and young children, and the barium will pass into the ileum readily. I have seen a number of definite intussusceptions shown by x-rays and, after opening the abdomen, we could see the small markings on the ileum and the damaged bowel where the intussusception had been before it had released itself. However, I again take the position that it is much better to operate in such a case and find that the intussusception has reduced itself than to delay surgery and discover a badly damaged or gangrenous bowel from an intussusception which has been left too long without surgical intervention. I want to emphasize that if there is the slightest doubt one never makes a mistake in operating in such a case.

I have observed 3 cases in boys between the ages of 6 and 10 years in whom there was a chronic intussusception without strangulation of the bowel, which produced only mild symptoms of obstruction. A tumor could be felt in the abdomen of these patients, and there was a history of mild cramps for several weeks and in 1 instance for several months. One of these patients had been operated on three times previously for recurrent intussusception. Not one of these intussusceptions had produced a complete obstruction, and the intussusception was from 2 to 4 inches in length, where the ileum had intussuscepted through the ileocecal valve into the colon. To prevent a recurrent intussusception, I have found that the best surgical procedure is to divide the parietal peritoneum, suture it over the ileum with strips of parietal peritoneum, which hold the ileum in one direction, and then suture the parietal peritoneum in the opposite direction over the cecum. This makes the ileum retroperitoneal more or less for several inches and prevents recurrence of the intussusception. In all cases of intussusception in which the ileum and cecum have extremely loose mesenteries, I find it advisable to do this simple procedure to prevent recurrence.

Mesenteric Adenitis.—This condition is commonly mistaken for appendicitis, since the children have all the classic symptoms which would seem to indicate an

Read in a symposium on "Abdominal Pain in Children" before the Section on Pediatrics at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 15, 1944.

acutely inflamed appendix: pain, local tenderness, with varying elevations of temperature, and a high white blood cell count. However, the pain in these cases can be differentiated from appendicitis, as the attacks are intermittent and usually last only from a few minutes to half an hour with the pain confined to the area around the umbilicus. Many of these patients are operated on with a diagnosis of subacute appendicitis or periodic attacks of appendicitis.

Many times I have operated for supposedly acute or subacute appendicitis and found a mesenteric adenitis of tremendous extent, with hundreds of glands which vary from pea to walnut size but with the appendix unaffected. I have never seen any harm from such surgery and I have always removed the appendix in such cases. On the other hand, there is a more severe type of mesenteric adenitis in which the glands are extremely reddened; the patient has a high temperature and a rigid abdomen, such as one would find in a case of acute suppurative appendicitis. I have operated in

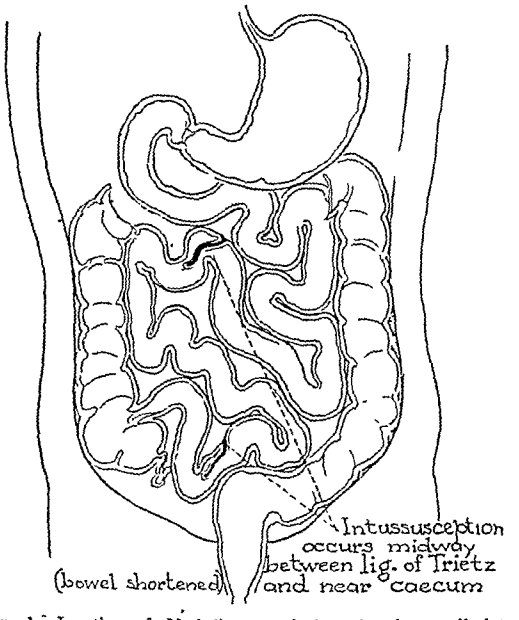

Fig. 1.—Location of Meckel's diverticulum in the small intestine, midway between the ligament of Treitz and the ileocecal valve, which can produce intussusception.

cases in which one large gland in the mesentery near the ileocecal valve was suppurating and had broken down; and, in 4 cases, several of these glands had broken down, suppurated and produced a peritonitis of quite a virulent type. In all these cases recovery followed operation, with simple drainage of the peritoneum.

Acute Inflammation or Rupture of Meckel's Diverticulum.—Probably the next most common condition to be differentiated from acute appendicitis is acute inflammation or rupture of Meckel's diverticulum. While, in a large number of cases, the Meckel's diverticulum is located on the ileum within 4 to 12 inches from the ileocecal valve, I have seen a number of cases of perforating Meckel's diverticulum located midway between the ligament of Treitz and the ileocecal valve (fig. 1). In 2 cases the Meckel's diverticulum inverted itself into the lumen and then, acting as a tumor in the lumen of the bowel, produced a double intussusception of the small intestine and in another case produced a triple intussusception (fig. 2). In all these cases acute pain and typical symptoms of acute appendicitis were present. The acute inverted diverticulum was excised by an elliptic incision made in the longitudinal axis of the bowel after the intussusception had been released and then sutured transversely with two layers of silk suture (fig. 3). The intussusception in these cases is very easily released by the usual method of forcing

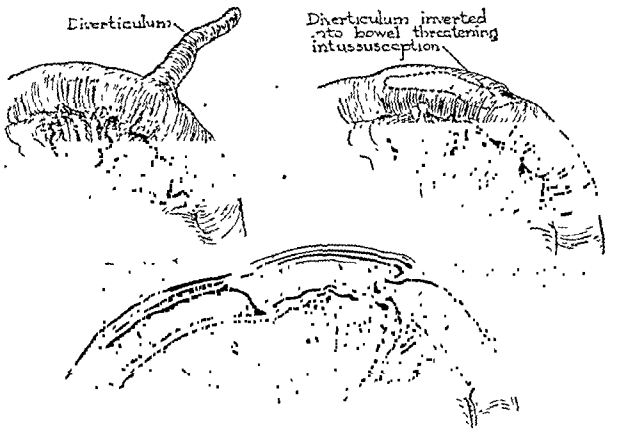

Fig. 2.—Meckel's diverticulum, the diverticulum inverted into the bowel threatening intussusception; and diverticulum with intussusception.

the bowel out as we do with a typical ileocecal intussusception, and I have never seen any serious damage to the bowel result from these small bowel intussusceptions in comparison to the serious damage which can result from an ileocecal intussusception. I have noted a number of cases in which the Meckel's diverticulum was acutely inflamed and, in addition, there had been much bleeding and a very pronounced anemia.[1] The blood in these stools was uniformly mixed, whereas, if the patient had bled from the large bowel, the blood would have been on the outside of the stool. This condition can be diagnosed if there is a history of constant presence of blood in the stool and the patients have pronounced anemia and local tenderness. Usually, in these cases of bleeding Meckel's diverticulum, duodenal or gastric mucosa is present, and the lesion is

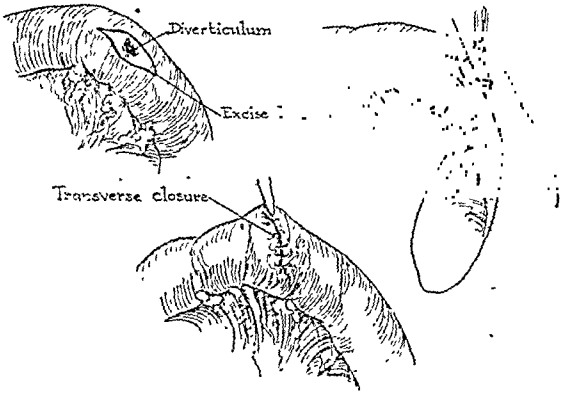

Fig. 3.—Diverticulum excised in the longitudinal axis of the bowel, and the defect in the bowel closed transversely to the longitudinal axis of the bowel.

similar to the gastric or duodenal ulcer infiltration that is seen in the stomach or duodenum. It is important that these patients have repeated blood transfusions, especially before operation, as these cases are not as acute as cases of appendicitis, and supportive measures can be taken before surgery.

1. Strauss, A. A., and Abt, I. A.: Meckel's Diverticulum as a Cause of Intestinal Hemorrhage, J. A. M. A. 87:99 (Sept. 25) 1926.

Intestinal Congenital Anomalies.—It is also difficult to differentiate the intestinal congenital anomalies that occur in young children shortly after birth and in the first year of life, such as lack of rotation and fixation of the mesenteries of the cecum, colon and intestine to the parietal peritoneum.

The anomalies that occur in the upper intestinal tract, such as atresia of the pylorus or congenital pyloric stenosis, play no particular role in this paper, as these conditions do not produce pain, and their main symptoms are regurgitation and vomiting. However, the atresia and strictures of the lower portion of the small bowel, colon and rectum play an important role in producing pain, abdominal distention and vomiting; and in many instances if they are not immediately relieved they can produce death, because they damage the bowel and the intestine. This condition is not compatible with life and must be immediately relieved. I have recently had 2 cases of complete intestinal atresia in which about 4 inches of the small bowel was atresic. A resection was done with a side to side anastomosis, and both patients made excellent recoveries.

This is, however, one anomaly that I should like to call attention to, namely, lack of rotation of the colon

Fig. 4.—Parietal peritoneum sutured on in strips to prevent intussusception of the ileum and cecum.

and absence of fixation of the mesenteries of the cecum, colon and intestine to the parietal peritoneum. The symptoms from this anomaly can occur any time during childhood, and even later in life. I have operated in 5 cases of acute conditions of the abdomen in which there was no fixation of the mesenteries of the small intestine and colon to the parietal peritoneum, and the only attachment of the intestine was where the large blood vessels normally enter the mesentery at the celiac axis. There was longitudinal rotation or volvulus, with from five to six complete twists in both the small and the large bowel. The intestine appeared blue and cyanotic but not strangulated. The small intestine, as well as the large bowel, was easily untangled and was then attached in normal position by dissecting free small areas of the parietal peritoneum and suturing them to the colon and its mesentery to hold them in correct position. Similar attachments were also made to the small intestine in a half dozen areas. All of these patients made uneventful recoveries, and 1 whom I have been able to follow for seventeen years is in perfect health and an athlete at one of our universities. This shows that if the attachment of the organs is carefully made there is not likely to be a recurrence of the condition.

There are many other anomalies in children, aside from those due to lack of rotation of the cecum, such as atresias of the ileum near the ileocecal valve or congenital absence of the rectum or sigmoid, and it is important to keep all these factors in mind when one examines a child for an acute condition in the abdomen. Therefore I believe that, in consideration of these factors, if there is the slightest doubt regarding the diagnosis, operation should be performed on children much more readily than on adults, for whom such conditions can be ruled out.

Infections.—Pneumococcic peritonitis and other types of infections from the vagina, uterus and oviducts must be kept in mind in cases in young girls. The symptoms of pneumococcic peritonitis are sometimes more insidious, as the mother will state that the child had a mild stomach ache for a few days, which became more severe, until the abdomen was rigid and boardlike. The presence of a characteristic mucous type of secretion when the abdomen is opened, and a smear, often will diagnose the condition as pneumococcic peritonitis. If it is not of pneumococcic origin, gonococci or other organisms will be found. Before the use of the sulfonamide drugs, pneumococcic peritonitis had a high mortality, from 50 to 90 per cent, but this has been remarkably reduced with the use of sulfonamide compounds. In spite of chemotherapy, the treatment in these cases, in my opinion, is drainage of the peritoneum to relieve the intra-abdominal tension. I do not believe in closing the abdomen without drainage because the sulfonamide drugs are now available.

It is difficult to differentiate between pneumonia and infections of the pleura, which often can produce rigidity and pain in the right side of the abdomen. It is only with a very careful examination of the chest and roentgenograms that a correct diagnosis can be made to determine whether the pain is produced from a chest condition or from an abdominal process.

Ovarian Cyst.—Ovarian cyst of the right and the left side is much more common in young girls than has been realized. It is not unusual for a surgeon to operate for subacute appendicitis through a gridiron incision, remove a mildly inflamed appendix and close the abdomen, leaving an ovarian cyst. I therefore have made it a routine procedure in all cases of appendicitis in females to palpate the right ovary and tube, the uterus and the left ovary and tube, except in the presence of an acute suppurative appendix. In a large number of cases in which I was not satisfied that the appearance of the appendix was sufficient to explain the symptoms of the patient I have found a small twisted ovarian cyst on the right or left side. I usually operate through a gridiron incision in all cases of appendicitis, and I have had no difficulty in palpating both tubes, ovaries and the uterus through this incision. If a routine examination of these organs is made when a subacutely inflamed appendix is removed, the mistake of overlooking an ovarian cyst is not apt to be made. The symptoms of a twisted ovarian cyst, as a rule, are not as severe as those of acute appendicitis; but I have seen cases in which the pain, white blood cell count and temperature were as high and the symptoms were as severe as those in acute suppurative appendicitis. The surgical procedure in these cases is to extend the gridiron incision into a right rectus incision by splitting the rectus sheath downward. In the case of a simple ovarian cyst I prefer to leave the base of the ovary and merely resect the cyst, but if the ovarian cyst

is badly twisted it is best to remove the ovary, and in most instances, the tube.

Rupture of Graafian Follicle.—Another condition of the ovaries that must be taken into consideration is the rupture of a graafian follicle, with severe hemorrhage. I have seen 27 cases in young girls of bleeding ovaries due to rupture of a graafian follicle. The abdomen was full of blood and there was a mild anemia, and all the typical symptoms of acute appendicitis were present, such as localized pain, high temperature and rigidity of the abdomen, which was often very evident. In many instances it is almost impossible to differentiate between these two conditions until the abdomen is opened. Usually the procedure in these cases is careful suture of the bleeding ovary so that it is absolutely dry. I believe that the patient will have less reaction if all the blood is aspirated from the abdomen by suction apparatus. In these cases transfusion is usually indicated after operation. If the patient's condition is quite good, I remove the appendix so as to spare the patient this procedure at any future time.

Gallbladder Disease.—Gallbladder disease, gallstones and obstruction of the common duct are much more common in young children than was thought at one time. It is extremely difficult at times to differentiate between an acute cholecystitis and a high lying appendix with a nonrotated cecum. If gallbladder disease is suspected and the condition persists, exploration is indicated. If stones are present it is best to do a cholecystectomy; but, if the condition is very serious, removal of the stones and drainage will probably have the lowest mortality. Obstruction of the common duct may be due to lymph glands obstructing the common duct or to stones. In a boy aged 11 a stone was located in the ampulla of Vater. The common duct was large and there were no stones in the gallbladder. The boy had repeated attacks of pain and a severe diabetes mellitus. The stone was removed, and the diabetes completely disappeared. I also found that, as a result of these previous attacks, a small amount of fat necrosis had formed in the abdomen. It is well, therefore, to consider gallbladder disease and pathologic change in the common duct in the presence of acute abdominal pain in children.

Congenital Megacolon or Hirschsprung's Disease.—While this anomaly is not common it must be considered in cases of acute abdominal pain, as many times there is an acute dilatation of the sigmoid portion of the megacolon, or a volvulus, with strangulation of its blood vessels. Usually the diagnosis can be made from a previous history of megacolon or from the pendulous distended abdomen produced by the large colon. In these cases I have always preferred to do an immediate simple loop ileostomy. I make the ileostomy opening immediately at operation and pass a rectal tube through the ileocecal valve into the colon, using a suction apparatus to decompress the colon. I prefer ileostomy to cecostomy because it avoids handling of the tremendously large colon. After the decompression has been effected by ileostomy, a left rectus incision is made and the rotated megacolon corrected and left alone if the blood supply has not been strangulated. However, if the blood supply has been cut off and the bowel damaged beyond repair, a local resection may have to be done by the obstructive clamp method. I prefer this operative procedure because I believe that the fundamental factor for the immediate relief of the patient's condition is the decompression of the colon.

Subacute and Chronic Ulcerative Colitis.—While this condition is comparatively rare in infants and children, the possibility of its presence must be considered in the case of an acute condition in the abdomen. In fact, some of the most severe forms of the disease have occurred in young children and infants. A history of cramps and pain and the presence of mucus, pus and blood in the stools is quite characteristic, and a careful proctoscopy usually makes the diagnosis comparatively simple. In my judgment, if the disease does not subside within a few weeks an immediate simple loop ileostomy is indicated. I know of no other condition of the colon which will show more decided improvement from immediate ileostomy. I believe that an immediate ileostomy is the only means by which the progressive pathologic course of the disease can be arrested and the destruction of the colon prevented. If the disease subsides, which it has a greater tendency to do in children and infants than in older persons, the ileostomy can easily be closed. By this procedure not only the patient's colon but his life can be saved. Medical treatment in these cases has little to offer and has been overdone by being continued until the colon is completely destroyed. In 4 of 5 cases in young children the ileostomy was closed within four years and the patients have remained perfectly well. In the fifth case the ileostomy is still present, as the colon contracted and strictures formed to such an extent that closure was impossible.

Strangulated Hernias.—In the diagnosis of an acute condition in the abdomen, this condition is sometimes overlooked, especially the incarcerated or strangulated femoral hernia in infants, because of the fatty condition of the abdomen in the inguinal and pubic regions.

INDICATIONS FOR OPERATION

Acute appendicitis is quite rare in children under 2 years of age, although I have seen 2 cases in infants aged 6 weeks and a fairly larger number in children between 6 and 12 years than in those between the ages of 1 and 6. It is sometimes extremely difficult to make an early diagnosis of this condition in children between 1 and 6 years of age, first, because of the fat abdomen and, second, because of the difficulty in differentiation from other conditions such as enterocolitis, peritonitis of primary type, acute mesenteric adenitis and the exanthemous fevers. I have seen a number of cases of appendicitis in which measles and severe scarlet fever were complicating conditions. It is important to make an early diagnosis of acute appendicitis in young children because the condition takes an entirely different course than that in an adult. I have often called attention to the fact that the appendix ruptures much earlier in children than in adults and is more likely to produce a general peritonitis. This is because the wall of the appendix in children consists chiefly of elastic tissue and has less connective tissue than that of adults, and, if the lumen becomes obstructed by a fecalith or inspissated material, the appendix will rupture much sooner. I have also noticed many more fecaliths and inspissated material in the lumen of the appendix in children than in adults. The peritoneum in children has less resistance to a peritonitis and there is little omentum in the region of the appendix to serve as protection. Then too the mother is more likely to give the child castor oil or another purgative for a so-called stomach ache and this, of course, is an additional factor which may endanger rupture and general peritonitis in cases of acute appendicitis. Needless to say, in children

in the first years of life appendicitis must be differentiated from the respiratory infections which are common at that age. The direct symptoms of appendicitis, such as pain, localized tenderness and rise of temperature, vary little from those in adults except that the temperature is usually higher and the vomiting more pronounced. A rectal examination should be made in addition to examination of the abdomen. It is common to obtain a leukocyte count of 12,000 to 20,000 with 85 to 90 per cent polymorphonuclears. A urinalysis should be done, although red blood cells in the urine do not always rule out appendicitis. In fact, gross blood appeared in the urine in 3 cases in which the appendix was retrocecal and was localized over the ureter, and the inflammatory process had infiltrated into the ureter.

In the surgical treatment of appendicitis in young children, immediate and early operation is the most important factor in securing good results and a low mortality rate. I do not believe in delay of operation or use of the so-called Ochsner method of treatment, except for a few hours in which the patient should be given intravenous injections of glucose and blood transfusions to get him in good condition. I prefer the McBurney gridiron incision to any other method; and if there is any difficulty the incision can always be extended above or below into a right rectus incision. I do not believe in draining abscesses without removal of the appendix and inversion of the stump with a wax silk purse string. I think it is a great mistake to drain the abscess and leave an infected appendix with enteroliths and a sloughing appendix within the peritoneal cavity. Young children do not stand well absorption from such a source, and it takes little time to peel off the appendix in almost any position. It adds little to the operation and rids the patient of the infectious process. I have never drained an appendical abscess in a child without also removing the appendix, and after a rather extensive experience I still believe that this is the best method of treatment. I also think it is a mistake merely to remove the appendix and ligate with chromic catgut or silk without also inverting the stump, especially in the case of an infected appendix, as fecal fistulas are bound to develop at the stump where the appendix was ligated when drainage is established. I have never seen a fecal fistula develop since I have adopted the procedure of ligating the stump and inverting it with a purse string of wax silk. I do not believe in closing the abdomen without drainage in cases of very severe suppurative appendicitis, especially if the appendix has ruptured or there is a severe local peritonitis. Since sulfanilamide has come into use, many surgeons have closed the abdomen in such cases and depended on the drug. I use sulfanilamide but in addition employ drainage, especially in cases in which the appendix has ruptured. Also in occasional cases of severe localized peritonitis in which the bowel shows a great deal of grayish exudate and inflammation I believe it is safer to establish drainage than to close the abdomen. I prefer to give glucose and blood intravenously in cases of peritonitis and administer nothing by mouth until the abdomen has become soft. I use the Wangensteen method only when I feel that it is indicated; that is, when the peritonitis is severe and there is a good deal of intestinal distention. I have also used a rectal tube with a Wangensteen suction apparatus to keep the colon collapsed in cases where there was much abdominal distention. In 4 cases of severe appendicitis with rupture and pronounced peritonitis, in which the bowels and the stomach were tremendously distended, I did an immediate loop ileostomy to collapse the ileum, in addition to removing the appendix. I reduced the colon by passing a rectal tube through the ileocecal valve. Four patients with severe appendicitis which had ruptured and produced peritonitis had been critically ill from five to eight days; the bowel and stomach were tremendously distended and they were in a moribund condition. I did an immediate loop ileostomy and the patients recovered. Large amounts of glucose intravenously and repeated blood transfusions are important supportive measures for a critically ill child with peritonitis following rupture of the appendix. Young children have elastic vascular systems and stand intravenous fluids well, and they show the good effects of this treatment much more quickly than do adults.

CONCLUSIONS

The difficulty in making an accurate diagnosis of an acute condition of the abdomen in infants and children is due to the following factors:

1. The differentiation between the exanthematous diseases of early childhood.
2. The anomalies that occur in infancy in the intestinal tract and the abdomen.
3. The fatty condition of the abdomen in infants and children in the inguinal and pubic regions, which makes palpation and percussion difficult.

Early diagnosis and operation are the important factors for lowering the mortality rate of appendicitis in children, and more harm can result from the delay of operations than from operations performed on an erroneous diagnosis.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. CAMPBELL AND STRAUSS

DR. HERBERT E. COE, Seattle: For several years Dr. Campbell has been making valuable contributions to the care of children by pointing out repeatedly the signs and symptoms of uropathy. I confess to surprise at his statement that one eighth of all children have some type of urogenital anomaly. He also says "Most acute abdominal pains demand surgical consideration." Sylvester several years ago, in reporting 1,000 cases of acute abdominal pain, found 80 per cent nonsurgical. I wonder if Dr. Campbell's statement should not read "Most acute abdominal pains which reach the surgeon demand surgical consideration." Especially deserving of emphasis is his insistence that children with nonemergency pain or with continued or recurring pain of obscure origin be given the benefit of a comprehensive urologic examination. Acute appendicitis is too often a lazy diagnosis and chronic appendicitis a wastebasket diagnosis, to be condoned. His recitation of the case of "left sided chronic appendicitis" illustrates the extent to which some may go to make the appendix the culprit. It is poor policy to hurry the examination. Ten minutes spent in gaining the confidence of the child will insure the acquisition of all necessary information in the succeeding three minutes, whereas a fifteen minute struggle results only in physical and mental exhaustion for all concerned. An attractive toy, apparently carelessly dropped on the floor, will demonstrate characteristic pain reactions in muscles or abdomen and avoid a negativistic response to a question or a command. A suspected point of abdominal tenderness should be approached from a known nontender area, and the rigidity due to a cold hand, too vigorous prodding or fear of the examiner should be avoided. When the rectal examination is necessary, it should be conducted with utmost gentleness and plenty of lubrication if the results are to be of any significance. Abdominal tenderness in an infant may often be differentiated from peristaltic pain by requesting the mother to hold the patient firmly against her shoulder. Posture and actions are often presumptive diagnostic points in estimating

abdominal tenderness, as the child with a tender appendix will lie quietly whereas one with colic or early obstruction usually tosses about. The periodicity of the pain of peristaltic rushes suggests the obstructive type of lesion or the functional condition rather than the inflammatory one, but in the presence of definitely localized tenderness such periodic pain directs attention to an acutely inflamed appendix without protective adhesions. Moderate, persistent pain over a period of hours or days suggests the pressure of a tumor, a mesenteric drag or slow distention of the peritoneal covering of a viscus. Severe periodic right sided pains with relatively normal intervening periods require careful palpation along the course of the ureter, palpation over the bladder and the gonads and all laboratory aids to diagnosis. Much as I dislike the term, exploratory laparotomy must occasionally be performed, and the surgeon must have well in mind the various conditions that he may encounter. Dr. Strauss's principle that delay while attempting fine points of diagnosis is far more dangerous than opening a normal abdomen is vitally important and should be a fundamental concept with all who treat abdominal pain in children.

DR. ERNST WOLFF, San Francisco: Many children are seen as suspects for so-called subacute appendicitis, who complain about abdominal pain, mostly in the afternoon, but have no fever nor abdominal rigidity but irregular bowel movements. These children lose their symptoms on a good regimen of adequate diet and regular elimination early in the day. Nobody up to now has mentioned the psychosomatic angle of abdominal pain as a leading symptom. We have learned from psychologists and psychiatrists that the gastrointestinal tract is the shock receiving organ, which is frequently hit by emotional upsets in childhood. It is an everyday experience in pediatric practice that emotional stresses within the family, as between parents and children, and emotional upheavals in the lives of children provoke abdominal pain and require psychotherapy.

NODULAR VASCULAR DISEASES OF THE LEGS

ERYTHEMA INDURATUM AND ALLIED CONDITIONS

HAMILTON MONTGOMERY, M.D.
PAUL A. O'LEARY, M.D.
AND
NELSON W. BARKER, M.D.
ROCHESTER, MINN.

There is a group of diseases which involve primarily the legs, characterized by the presence of nodules and sometimes by ulceration and which are associated with varying degrees of involvement of the blood vessels and fibrosis. These diseases, which have many features in common, are nodular vasculitis, erythema induratum, erythrocyanosis and pernio, erythema nodosum, panniculitis, recurrent idiopathic thrombophlebitis, and indurated cellulitis and ulceration secondary to chronic venous stasis.

Our especial interest in these diseases was aroused because they have certain clinical features in common which often make a differential diagnosis difficult or impossible on clinical grounds alone. Likewise it is difficult to correlate the vascular involvement, which may be of varying degree and sometimes of different types in each disease with the clinical findings. Furthermore, histopathologic studies of tissue excised from the nodules and ulcers have not simplified the problem, especially as to the etiologic relationship of tuberculosis in some of them. If typical tubercle formation with varying amounts of central caseation and zones of epithelioid cells, lymphocytes, plasma cells and Langhans' type of giant cells was demonstrable in all cases and if the diagnosis of tuberculosis could be substantiated by the demonstration of Mycobacterium tuberculosis in sections of tissue or by animal inoculation, the etiologic problem would be simplified considerably. It is generally recognized that the presence of collections of epithelioid cells and only a few giant cells is not diagnostic of cutaneous tuberculosis; such histologic changes occur in many nontuberculous conditions such as tuberculoid syphiloderm and tuberculoid forms of leprosy. Conversely, in typical cases of tuberculous erythema induratum pathologic examination may fail to reveal evidence of tuberculosis but simply reveal a nonspecific granulomatous lesion with varying degrees of fatty atrophy, fibrosis, vasculitis and foreign body giant cell reaction. We have observed a case in which such a histopathologic picture was present. Notwithstanding the absence of a true tuberculous structure, the disease was proved to be tuberculous by inoculation of guinea pigs. Accordingly, we are in accord with Kyrle [1] in believing that Mycobacterium tuberculosis may produce a banal nonspecific inflammatory reaction in some cases while in others the classic tubercle formation may be present. When the histopathologic findings are presumptive, concomitant evidence of the existence of tuberculosis as revealed by inoculation of guinea pigs, tuberculin tests and roentgenologic examination is essential for diagnosis. In cases in which the diagnosis is doubtful, we have found that observation of the patients for a long time is advisable because, although evidence of the existence of tuberculosis may be lacking when the patient is first seen, repeated examination may subsequently show the presence of tuberculosis in the cervical lymph nodes, peritoneum or elsewhere. Two of us and Brunsting [2] recently observed a woman aged 54 with nodular vasculitis in whom clinical, pathologic and bacteriologic examination had failed to disclose any evidence of tuberculosis. When the patient was seen six months later she had tuberculous cervical adenitis (proved histologically) and a strongly positive tuberculin reaction.

The ideal procedure for an investigation of this type would consist, as Sulzberger [3] suggested, in the removal of many large specimens of the cutaneous lesions in different stages of development. These specimens should be examined microscopically and a portion of each specimen should be used to inoculate as many as 10 guinea pigs. We have adopted the following criteria as evidence of the tuberculous origin of these diseases: (1) a positive reaction of guinea pigs to inoculation; (2) the presence of accepted histopathologic changes of tuberculosis including the presence of typical tubercles, with or without demonstration of Mycobacterium tuberculosis, and not merely collections of epithelioid cells and foreign body giant cells or the presence of caseation necrosis without the formation of tubercles; (3) contributory evidence such as proof of active tuberculosis elsewhere in the body or a history of previously recognized tuberculosis, positive roentgenologic findings or strongly positive tuberculin reactions, and (4) the clinical appearance and typical course of accepted types of cutaneous tuberculosis. These criteria

have been listed in the order of their diagnostic significance.

Although it is rare that all of these criteria can be demonstrated in the same case, they should be sought for.

Fig. 1.—*a*, nodular vasculitis in the leg of a woman aged 59; lesion of six months' duration; *b*, thickened walls of arterioles and venules at *X*; fibrosis and foreign body giant cell reaction in subcutaneous tissue (× 50).

This report is based on a study of the clinical, histopathologic and other laboratory data in 175 cases of nodular, and in some cases ulcerative, lesions of the legs and in 40 cases of recurrent idiopathic thrombophlebitis previously reported by one of us.[4] All of the 175 patients in the present series were white adults. In some cases the disease had been present for a long time, that is, it first had appeared at the age of puberty or when the patients were in the early teens. Negroes for whom a diagnosis of sarcoid or sarcoidosis was entertained and Negroes with cutaneous tuberculosis of the extremities were excluded from this study, as we believe they represent a distinct problem in themselves. In practically all of the cases a complete physical examination including roentgenologic examination of the thorax was performed in an effort to disclose evidence of tuberculosis. In many cases tuberculin tests were done by the intracutaneous method, by using purified protein derivative. A weak dilution of 0.00002 mg. was used, but in some cases a second injection of 0.005 mg. also was given. Animals were inoculated and cultures were made in a search for Mycobacterium tuberculosis in some of the recently observed cases, especially those in which a diagnosis of erythema induratum was considered.

NODULAR VASCULITIS

The nontuberculous origin of erythema induratum, especially the nodose nonulcerative form, as first exemplified by the case reported by Audry,[5] was further considered in the cases reported by Galloway[6] and Whitfield[7] at the beginning of this century. Our concept of nodular vasculitis corresponds well with the description given by Galloway and Whitfield in several articles. The nodose lesions are painful and occur chiefly on the calves of the legs of women 30 to 40 years old. They are seen only rarely among men or younger women and tend to clear up with rest in bed and elevation of the legs. Ulceration seldom occurs, but recurrence is common and a history of a previous or long-standing phlebitis is sometimes obtained. The lesions (fig. 1 *a*) have the same distribution as those of erythema induratum but are more painful and usually are of shorter duration. Histopathologically the nodules showed evidence of vasculitis with varying degrees of thickening and obliterative changes in both veins and arteries and a varying degree of fibrosis of the subcutaneous tissue, with collections of foreign body giant cells and atrophy of the fat but without definite tubercle formation (fig. 1 *b*). Audry, Galloway and Whitfield and other authors[8] were unable to demonstrate any clinical evidence of tuberculosis elsewhere in their patients, and animal inoculation failed to disclose Mycobacterium tuberculosis. In the cases reported by Whitfield there was failure to react systemically to doses of old tuberculin which caused febrile reactions in control cases of proved tuberculosis. Some of their patients

were observed for many years. Whitfield stressed the absence of systemic disease and the onset after 30 years of age, whereas Galloway emphasized the vascular changes. The nontuberculous origin of erythema induratum in some cases has been emphasized more recently by Ormsby [9] and Michelson.[10] Cases which we have regarded as cases of nodular vasculitis also have been reported at recent meetings of dermatologic societies.[11]

We would abandon the term "periphlebitis" or "phlebitis nodularis necrotisans" as suggested by Philippson,[12] because it has been used to represent both tuberculous [13] and nontuberculous [14] conditions. Furthermore, in many of the reported cases of periphlebitis nodularis necrotisans the arteries as well as the veins apparently have been involved.[15] We believe that some of these cases could more properly be grouped with cases of nodular vasculitis, whereas some of the other cases would fit in with cases of primary recurrent thrombophlebitis.

ERYTHEMA INDURATUM

We employ the term "erythema induratum" (Bazin) in the specific sense to designate a tuberculous process either of an ulcerative or of a nodose form. The disease usually is described as beginning with involvement of the calves of the legs of girls during adolescence, but it also may occur among boys and men and may start at any age in life (figs. 2 and 3). Erythema induratum also may be associated with other forms of hematogenous tuberculosis and has been grouped by one of us [16] under the heading of tuberculosis cutis indurativa, which includes papulonecrotic tuberculids.

The 175 cases in this series included 72 which, after correlation of clinical and pathologic findings, were classified as cases of erythema induratum. The age at the onset of the disease varied from the early teens to 65 years. Eleven patients were men. In 2 of the 11 cases the lesions were classic examples of the usual ulcerative form of erythema induratum occurring on the leg; in 5 of the cases there were nodose lesions without ulceration. In the remaining 4 cases cutaneous tuberculosis was present elsewhere; the tuberculous lesions included papulonecrotic tuberculids and scrofuloderma. Two of the women had lesions of erythema induratum on their legs and similar lesions on the arms and breast. A history of recurrent nodules and ulcers which occurred every winter and disappeared in the summer was obtained in several of the cases (fig. 3). In a few cases the involvement was unilateral; in 2 cases there were superficial lesions which simulated ecthymatous ulcers and were comparable to tuberculides ulcereuses des membres inférieurs as described by Pautrier.[17]

In 21 of 25 cases of erythema induratum the intracutaneous tuberculin test (purified protein derivative) with a weak first dilution was positive. Mycobacterium tuberculosis was searched for in the examination of specimens of the skin in all of the cases of erythema induratum but was found in only 2. Inoculation of guinea pigs with portions of these specimens disclosed Mycobacterium in only 2 of 10 cases in which this test was performed. A negative result, however, would not rule out the presence of this organism, as such a negative report is of no significance.

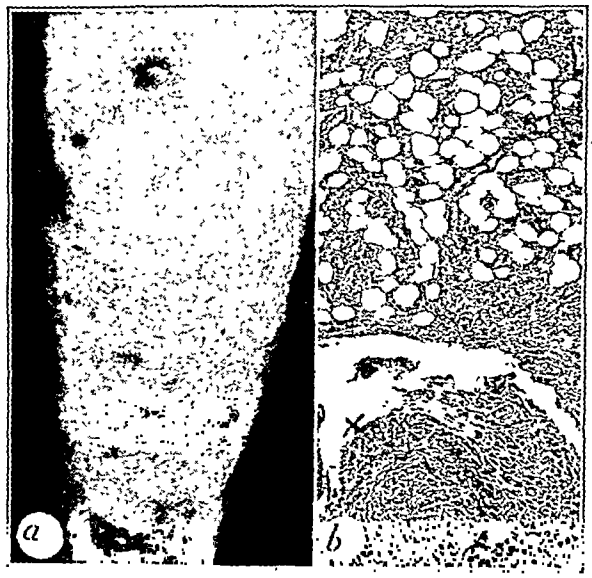

Fig. 3.—*a*, erythema induratum on leg of a woman aged 31; recurrent nodules, ulcers and livedo had occurred each winter for eighteen years; *b*, large occluded vein in subcutaneous tissue at *X*; fibrosis and fatty atrophy (× 30).

It is generally recognized that in cases of erythema induratum the histopathologic changes are not always classic. In our experience a nonspecific granuloma with varying degrees of vasculitis has been present in somewhat more than 30 per cent of cases. Writers, including Volk,[18] Gans,[19] Kyrle [1] and Pautrier,[20] all have emphasized that the histopathologic changes are not always characteristic, and they have spoken essentially of the following three types of histologic reactions seen in cases of erythema induratum: (1) formation of typical tubercles with caseation in the center of the tubercles (fig. 2), (2) a severe degree of necrosis of the fat, both acute and chronic in type, with varying degrees of vasculitis and foreign body giant cell reaction and (3) a process similar to the second but with extensive fibrosis rather than necrosis of the fat pre-

dominating. Gans [19] regarded fibrosis as a late stage in the disease. Multiple sections of wide deep specimens which include subcutaneous tissue may be necessary before typical tubercles can be demonstrated. More than one specimen often is necessary for diagnosis.

A review of the literature of recent years indicates that little attention has been paid to the vasculitis present in erythema induratum, which formerly was described as affecting chiefly the veins and to a lesser degree the arteries. We observed some involvement of the veins and arteries in all of our cases (figs. 3 and 4). Varying degrees of periarteritis, endarteritis, panarteritis and phlebitis of the same types can be seen in erythema induratum involving not only the arterioles and venules but also at times involving the larger vessels in the subcutaneous tissues. As a result of necrosis of the fat (panniculitis) or extensive fibrosis secondary to the vasculitis, vascular changes may predominate to the exclusion of any formation of tubercles. At times there may be a necrotizing arteritis or a hyaline or fibrinoid necrosis of the arterial walls involving the media and intima which is suggestive histologically of periarteritis nodosa but is not associated with evidence of systemic disease. Varices that may be associated with lesions of erythema induratum are usually readily distinguished from the vasculitis seen in erythema induratum by the microscopic appearance, including the wavy walls and irregular pattern of the fibrosis that is present.

ERYTHROCYANOSIS AND PERNIO

Telford [21] defined erythrocyanosis as a reddish blue discoloration of the skin seen on the lower half of the legs of girls and young women, which is associated with indurative nodules which may break down to form small ulcers and undergo involution with residual scarring. Most of the affected women are stout and have a florid appearance and large legs. He compared the process

Fig. 4.—Typical examples of erythema induratum with vasculitis in subcutaneous tissue: *a*, obliterative changes in vein and artery (× 75); *b*, thickening of wall of vein, proliferation of endothelium but preservation of elastic tissue; arterioles also thickened at *X* (× 50).

to vascular disturbances in the leg in anterior poliomyelitis in which nodules develop in the winter time but later persist the year round with subsequent development of ulcers. Telford expressed the opinion that Bazin's disease (erythema induratum) is not of tuberculous origin and is in no way different from the condition he called "erythrocyanosis." He was unable in his cases to demonstrate a tuberculous origin either clinically, pathologically or by animal inoculation. In

Fig. 5.—*a*, pernio or erythema induratum (?) on the legs of a woman aged 29; painful nodules had recurred each winter for thirteen years; the ulcers, which had been present for one year, are deeper than those observed in most cases of pernio; *b*, obliterative vasculitis, fibrosis and caseation and fatty atrophy in subcutaneous tissue (× 35).

describing the microscopic appearance of erythrocyanosis he mentioned foreign body giant cells, obliterative vascular changes including thickening of all the coats of the arteries, necrosis of the fat and finally formation of fibroblasts and granulation tissue. He said that unlabeled sections of tissue of patients who have erythrocyanosis, Bazin's disease, anterior poliomyelitis and necrosis of the fat of the breast cannot be separated into their respective groups by histopathologic examination alone. He also said that tissues have a limited method of response and one should depend essentially on the clinical course and appearance of the disease for diagnosis. Seventeen of his 19 patients with erythrocyanosis remained well after sympathectomy.

Telford [21] apparently opposed the concept that erythema induratum is due to tuberculosis. Certainly, many of his illustrations, especially his figures 3, 4 and 5, would be acceptable as representing early but definite formation of tubercles, while other photomicrographs he included do not differ from those showing the nonspecific changes frequently seen in erythema induratum.

21. Telford, E. D.: Lesions of the Skin and Subcutaneous Tissue in Diseases of the Peripheral Circulation, Arch. Dermat. & Syph. **36**: 952-963 (Nov.) 1937.

McGovern and Wright,[22] under the title Pernio:[23] a vascular disease, reported cases which they regarded as similar to those reported by Telford. They pointed out that in Bazin's original monograph there were reports of several cases in which the description fitted that of pernio rather than that of erythema induratum but that, when Bazin originally described the condition, Mycobacterium tuberculosis had not been discovered. McGovern and Wright said that the onset of the disease was associated with painful nodules and indurated lesions on the legs of girls in adolescence, that it was precipitated by exposure to cold and that it tended to persist throughout the winter and disappear in the summer. A serosanguineous to purulent exudate is frequently followed by the appearance of superficial ulcers which may not clear up in the summer in cases in which the disease has been present for a long time (fig. 5). The internal malleolus and the calf are sites of predilection; however, the feet and toes, which rarely are involved in cases of erythema induratum and nodular vasculitis, may be involved by erythrocyanosis or pernio. McGovern and Wright compared their cases to the cases of frostbite reported by Perutz,[24] whose patients were women. In the cases reported by Perutz the inner aspects of the knee joints were involved and the condition was designated as "erythrocyanosis crurum puellaris." McGovern and Wright regarded pernio as a vascular disease affecting the smaller vessels of the skin and associated with terminal sclerodermatous changes. They described angiitis of the smaller veins, necrosis of fat and giant cells which were not associated with evidence of tuberculosis.

In both erythrocyanosis and pernio there are recurrent attacks which occur in the winter and disappear in the summer, which also is true in some cases of the tuberculous type of erythema induratum; however, it is true that the ulcers of pernio are usually more superficial than are the ulcers of erythema induratum and that the degree of inflammatory reaction is not as great in pernio as it is in erythema induratum

ERYTHEMA NODOSUM

Erythema nodosum is a much more acute process than any of the conditions that we have considered so far. The term is usually applied in this country to an acute disease associated with fever, malaise and arthralgia and characterized by relatively superficial tender nodules and plaques which occur on the legs but at times occur elsewhere on the body. The lesions last a few days to several weeks. They undergo involution without ulceration and leave a residual discoloration. There is a tendency for attacks to occur in the spring and autumn, and the disease has been associated with streptococcic infection, including foci of infection in the teeth and the tonsils. A chronic lesion resembling erythema nodosum may occur in association with other conditions such as syphilis and coccidioidal granuloma or as the result of administration of various drugs such as the bromides and sulfonamides. We are not concerned with these conditions in the present paper. In acute erythema nodosum,[25] microscopic examination reveals infiltration about the vascular network in the upper and middle portions of the cutis. The infiltrate consists chiefly of lymphocytes and polymorphonuclear leukocytes. The walls of the vessels are edematous, and at times there is an inflammatory hemorrhagic infiltration of the walls. There may be a relatively acute infiltration with atrophy and necrosis of the fat in the subcutaneous tissue. Secondary thrombophlebitis may supervene. According to Gans, when lesions persist for several weeks there may be atrophy of fat and a tuberculoid reaction without definite relation to tuberculosis.

We believe that the chronic forms of erythema nodosum which have been attributed to tuberculosis are actually examples of nonulcerative types of erythema induratum or types of nodular vasculitis.

PANNICULITIS

Like erythema induratum, relapsing, febrile, nodular, nonsuppurative panniculitis (Weber-Christian disease[26]) is often associated with bouts of fever. There are large subcutaneous plaques and nodules predominating on the trunk and thighs rather than on the legs, and subsequent subcutaneous atrophy results in depression of the skin at the site of involution. The condition is uncommon and occurs chiefly among women. The histopathologic changes are characterized by edema and necrosis of the subcutaneous fat with phagocytic cells of different types, which engulf the fat; there are a few multinucleated cells and an inflammatory reaction consisting of lymphocytes and polymorphonuclear leukocytes. As a rule there is little evidence of fibroblastic proliferation or of vasculitis; however, in recent articles the authors[27] have mentioned both of these conditions as well as edema of the walls of the arterioles, endothelial proliferation and even thrombosis. There apparently is no definite relationship between this disease and tuberculosis, although Tilden, Gotshalk and Avakian[28] and Shaffer[29] have reported atypical forms of the disease which are difficult to classify. Panniculitis of Weber-Christian disease is quite distinct from nodular vasculitis, erythema induratum, erythema nodosum, erythrocyanosis, pernio and thrombophlebitis, all of which, however, excepting primary thrombophlebitis, are associated with a varying degree of acute or chronic panniculitis in the subcutaneous tissues.

RECURRENT IDIOPATHIC THROMBOPHLEBITIS

Comment has been made that in many of the types of lesions just mentioned there may be an associated thrombophlebitis of the small veins and venules. In most cases in which thrombophlebitis affects medium sized and large veins the disorder is secondary to chemical or mechanical injury, local suppuration, blood dyscrasia, heart disease, carcinoma or varices, or it occurs after operations, childbirth or acute infectious disease and need not be considered in differential diag-

22 McGovern, Teresa, and Wright, I S Pernio A Vascular Disease, Am Heart J **22**: 583 605 (Nov) 1941

23 The use of the term "pernio" is somewhat confused in the literature, as the term has been applied to (1) lupus pernio (Besnier), which is a form of sarcoid, (2) lupus pernio (chilblain lupus Hutchinson), which is part of the picture of disseminated lupus erythematosus, and (3) erythema pernio (chilblains, frostbeulen, frostbites), which also has been called pernio and perniones The term "pernio" as used by McGovern and Wright apparently does not fit in with any of these uses except indirectly with the last one

nosis.[30] Primary recurrent idiopathic thrombophlebitis (thrombophlebitis migrans), however, should be considered in the differential diagnosis of the conditions mentioned in this paper. Primary idiopathic thrombophlebitis, unlike conditions already described in this paper, predominantly affects men rather than women (fig. 6 *a*). It is primarily a disease of small and medium sized veins and in many cases is identical to the thrombophlebitis seen in thromboangiitis obliterans except that the arteries are not involved. It is characterized by multiple discrete tender nodules which involve the lower extremities but also are found anywhere on the body. The nodules are quite tender, persist from seven to eighteen days and tend to occur in crops and to extend by segments to the larger veins. The lesions are more linear to palpation than circular and usually are

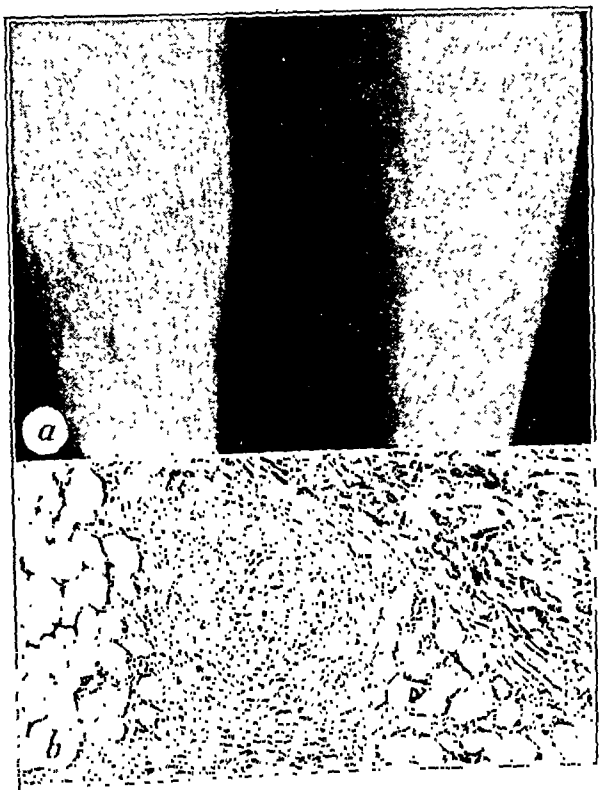

Fig. 6.—*a*, primary recurrent idiopathic thrombophlebitis of two years' duration on legs of a man aged 28; *b*, thrombosed vein in subcutaneous tissue with absence of inflammatory reaction (× 55).

smaller than are the lesions of erythema nodosum and erythema induratum. Constitutional symptoms are usually mild, and necrosis and ulceration of the nodules do not occur. The histopathologic changes in idiopathic thrombophlebitis include occlusion of the lumen by cellular thrombosis with severe infiltration of the wall of the vein, varying degrees of fibrosis of the wall and more particularly an absence of or very little inflammatory reaction of the tissue adjacent to the vein (fig. 6 *b*). The involved veins are usually larger than those affected in cases of nodular vasculitis, erythema induratum, erythema nodosum or panniculitis. Histologically, the relatively small amount of periphlebitic inflammatory reaction and the absence of necrosis of fat and fibrosis readily distinguish idiopathic thrombophlebitis from thrombophlebitis secondary to other conditions. Such sharp distinction, however, is not always possible clinically; at times, more than one condition may be present.

INDURATED CELLULITIS AND ULCERATION SECONDARY TO CHRONIC VENOUS STASIS

As a result of chronic venous stasis which follows iliofemoral thrombophlebitis or varicose veins of long standing, a subacute or chronic inflammatory reaction may occur in the lower third of the leg and produce a tender painful plaque-like induration of the skin and subcutaneous tissues. At times the entire circumference of the leg may be involved and have the appearance of a tight constricted anklet above which there is definite pitting edema. However, the most common site of involvement is just proximal to the internal malleolus. Ulceration may occur in these indurated regions. Secondary infection may occur, and considerable induration may be present in the margins of the ulcers. Ordinarily the differential diagnosis of these conditions and other nodular vascular lesions of the legs offers little difficulty, particularly if the history and findings indicative of previous iliofemoral thrombophlebitis or primary varicose veins are correctly evaluated. It is important to recognize that the primary etiologic factor in cases of cellulitis and ulceration secondary to venous stasis is the venous insufficiency.

SUMMARY

We have used the term "nodular vasculitis" to refer to relatively chronic, persistent or recurrent nodular lesions of nontuberculous origin occurring chiefly on the legs below the knees. The lesions occasionally result in ulceration and occur especially among women past 30 years of age but also affect younger persons. They infrequently affect boys and men. Histopathologically there is a definite vasculitis with varying degrees of obliterative changes in both arteries and veins together with necrosis of fat and fibrosis in the subcutaneous tissues. Cases reported by Galloway and Whitfield at the beginning of the century would belong in this group, as do other reported cases in which no evidence of tuberculosis has been demonstrable even when observations have been continued for a long period. We believe that nodular vasculitis represents an entity which is not due to tuberculosis although observation of affected patients for several years is necessary before conclusive deductions in regard to the cause of the disease will be possible.

A varying degree of vasculitis is a prominent feature of both the ulcerative and the nodular form of erythema induratum, and a specific histopathologic picture of tuberculosis is seen in about 70 per cent of the cases in which a clinical diagnosis of erythema induratum is made. The absence histopathologically of a tuberculous structure does not eliminate the possibility that a patient has erythema induratum (Bazin) because the duration of the lesions and of the disease and the site from which specimens are obtained for biopsy are important factors in establishing the diagnosis. Erythrocyanosis and pernio and erythema nodosum, panniculitis and stasis induration and ulceration all are associated with varying degrees of vasculitis and fibrosis and with varying degrees of acute or chronic panniculitis. There are many similarities between the conditions considered in this paper which necessitate correlation of the clinical, histologic and other laboratory data.

ABSTRACT OF DISCUSSION

DR. MICHAEL H. EBERT, Chicago: The classification of nodular lesions of the legs is often attended by great difficulty. There is a tendency to make the term erythema induratum a catch-all for obscure cases. In 1908 Schidachi, from Jadassohn's clinic, reemphasized the necessity of strict proof of the tuberculous origin of any given condition before it could be justly called erythema induratum. Painstaking studies by the departments of internal medicine, vascular diseases and pathology must be made to accumulate roentgenologic, pathologic, clinical, immunologic and experimental data before a decision can be arrived at. Erythema induratum, as the authors have shown, is a nodular vasculitis of tuberculous origin affecting the deeper vascular bed of the hypoderm and associated with varying degrees of panniculitis and fibrosis. They have reserved the term "nodular vasculitis" without any qualifying adjectives for the residuum of cases of similar symptomatology but of unknown or unproved etiology. The authors have emphasized the necessity for prolonged observation before passing final judgment on such cases. Generally speaking, they have pointed out that nodular vasculitis occurs in older women, is more painful, is of shorter duration, responds better to bed rest and has less tendency to ulcerate than erythema induratum. However, it has some tendency to recurrence. To say that erythema induratum is tuberculous does not completely explain its etiology. Its predilection for the legs is probably due to poor circulation and low resistance of the fatty tissue. There are still other things to explain: first, its predilection for young women and, second, its peculiar seasonal incidence. In addition to the immune state of the individual patient to the tubercle bacillus, it may be that functional vascular spasm plays a significant role. Cutis marmorata not infrequently accompanies erythema induratum, and this type of circulation is known to be the predisposing factor in livedo reticularis, a rare type of tuberculoderma. Tilford goes so far as to state that persistent functional spasm may result in organic changes in the vessels. Endocrine disturbance may be reflected through the vascular spasm. The increased evidence of erythema induratum in cold weather or cold damp climates would seem best explained on the basis of vascular spasm.

DR. JOHN H. LAMB, Oklahoma City: Stokes (*Arch. Dermat. & Syph.* **36**:412 [Aug.] 1937) presented a case of erythema induratum in which he stressed two important points: First, that some cases diagnosed as Bazin's disease often exhibit a pyogenic or allergic sensitizing factor with a possible tuberculosis which is demonstrated with difficulty. The patient he presented had many forms of therapy with no improvement. After the removal of an infected tooth, the lesions cleared for a year and a half. Second, the importance of support of the peripheral circulation with elastic bandages, rubber boots and gelatin boots. Greenbaum suggests equal parts of contractible and flexible collodion. A further report of a case of febrile nodular nonsuppurative panniculitis (*Oklahoma State M. J.* **33**:1 [Jan.] 1940) may have some bearing on the etiology of Weber-Christian's disease. A white girl, aged 11 when first seen in 1937, had panniculitis of the lower extremities. The disease was for the most part afebrile. New lesions appeared at irregular intervals until 1939. About six months after the appearance of the last lesion the patient reported to the clinic with the complaint of fever, stiffness, pain and swelling of her hands and some joint pain in the legs. The diagnosis was made of a juvenile equivalent of adult chronic infectious arthritis, Still's disease. This case aroused suspicion that there may be a possible relationship between this nodular disease of the lower extremities and rheumatoid arthritis. I agree with Drs. Montgomery, O'Leary and Barker that there is a group of nodular lesions of the lower extremity occurring in women over 30 years of age which is not Bazin's disease and can be classified under the term suggested, nodular vasculitis. Dr. Ebert's case of possible nodular vasculitis (*Arch. Dermat. & Syph.* **48**:212 [Aug.] 1943) also presented a history of rheumatic heart disease. I should like to ask the authors if there was a similar history in any of their cases. The association of rheumatism in many of these cases does not make the treatment of these conditions any easier or solve the problem of their etiology, since the causes of arthritis are many and varied, but it may give us a new approach to therapy in nodular lesions of the lower extremity.

DR. HENRY E. MICHELSON, Minneapolis: When discussing the various diseases that may occur on the lower part of the leg one must realize that the majority of such conditions are due either to stasis or to spasm of the blood vessels, with the resulting physiologic and pathologic changes. Most chronic conditions of the lower part of the leg are characterized by indurated plaques, and the more one studies the microscopic appearance of these plaques the more is one impressed with the fact that a pathognomonic microscopic picture is rarely present. The classic picture of erythema induratum is quite carefully simulated by other conditions. Therefore it is not easy to ascertain the etiology from the resulting pathologic condition. I am particularly concerned with the promiscuous injection of dilated veins. I have seen many examples of irreparable damage and persistent edema following the indiscriminate use of that method of treatment. Erythema induratum is part of a constitutional tuberculosis, and it may flare at the same time at which there is an exacerbation in the lung.

DR. FRED D. WEIDMAN, Philadelphia: I take it that "nodular vasculitis" is presented as a new clinical entity. It will receive much attention, whether one thinks of the quarters from which it comes in their physical or in their professional sense. That being the case, I beg to add another possible item that should not be overlooked as dermatologists come to evaluate this condition and determine its scope. I refer to the role of dermatophytosis. Thompson in New Haven and Naide in Philadelphia are experts in the field of peripheral vascular disease. They claim that dermatophytosis is the cause (or at least they go as far as they can without contending that they have positive proof on this point) that dermatophytosis produces an allergic mechanism which is responsible for spasms and thromboses of the blood vessels of the lower extremities. They intimate that this is the cause of Buerger's disease. Or, in other words, Buerger's disease is an allergic expression of dermatophytosis. I hold no brief for this thesis. I doubt that any of us would feel convinced until the matter has been yet more thoroughly studied, but at any rate it is worth remembering. In future studies of nodular vasculitis one should check for the presence of dermatophytosis. The microscopic changes are indeed similar.

DR. HAMILTON MONTGOMERY, Rochester, Minn.: None of our cases of nodular vasculitis presented any evidence or history of rheumatism or rheumatic cardiovascular disease. We do not know what nodular vasculitis is. It resembles erythema induratum but is apparently on a nontuberculous basis. The lesions are more acute and painful than those of tuberculous erythema induratum, but the lesions of nodular vasculitis are much more chronic in character than those in the common nontuberculous type of erythema nodosum. Primary idiopathic thrombophlebitis is to be distinguished from thrombophlebitis secondary to venous insufficiency and other conditions mentioned in the paper. We frequently see cellulitis and lymphedema in association with trichophytosis of the feet, but this is a distinct picture from the conditions which we grouped together in this presentation. Some authors, for example Telford, would regard all cases of erythema induratum as nontuberculous in origin and explainable on a vasospastic basis. We believe, however, that there is a tuberculous erythema induratum which should be distinguished from allied conditions which may simulate it.

Number of Practitioners in Ceylon.—A total of 928 physicians are in practice in Ceylon. About 405 of them are in government service. Private practitioners seem to be limited to towns. Medical missionaries are to be found in some sections. In 1938 the ratio of physicians to population was 1 per 6,500. In the same year there were about 3,500 registered native physicians who practiced medicine according to the precepts of the Ayur-Veda, the Hindu book of the science of health and medicine.—Simmons, James S., and others: Global Epidemiology, Philadelphia, J. P. Lippincott Company, 1944.

TREATMENT OF AMBULATORY PATIENTS WITH PENICILLIN SODIUM

PRELIMINARY STUDIES OF FUSOSPIROCHETOSIS

LIEUTENANT WILLIAM F. PEARCE
AND
CAPTAIN JOHN B. McDONALD
MEDICAL CORPS, ARMY OF THE UNITED STATES

The treatment of fusospirochetosis with penicillin sodium became apparent after the preliminary report by Mahoney and his co-workers [1] in 1943 noting the influence of penicillin therapy on the clinical manifestations and serologic reactions of patients with early syphilis. Also in 1943 Heilman and Herrell [2] found penicillin to be effective in experimental animals against other spirochetal infections, namely Leptospira icterohemorrhagiae of Weil's disease, Spirillum minus of rat bite fever and Spirillum recurrentis of relapsing fever. Following the confirmation [3] of these studies the use of penicillin against Spirillum vincenti became a reasonable sequence. With the more general use of this chemotherapeutic agent in various bacteriologic infections an apparent relationship between the condition of the gingivae and pharynx with the administration of penicillin was observed by Strock [4] and others in 1944. In such cases ulceration and bleeding of the gingivae disappeared after penicillin therapy was instituted, leaving the gums and pharynx free from inflammation; similar observations no doubt are being made by many users of penicillin today. Penicillin is an extremely powerful bacteriostatic and probably bactericidal agent that has the advantage of acting on most secondary invading organisms in the mouth and throat. A series of cases of fusospirochetal infection of the gingivae and pharynx was studied and is reported here using penicillin sodium as the paramount therapeutic agent.

Although this infection was treated systemically with penicillin sodium, the amount of active penicillin in the blood, measured by the power of the blood serum to effect bacteriostasis either by Fleming's [5] or Rammelkamp's [6] methods, was not computed; therefore clinical and bacteriologic response had to be utilized as the guide in therapy.

PROCEDURE

In this series 50 patients with fusospirochetosis were studied; these included 29 patients with Vincent's angina, 16 patients with Vincent's stomatitis and 5 patients having both conditions. Before penicillin therapy was instituted, the diagnosis was definitely established in each instance on the basis of the following criteria:

1. There was a history of sore throat (usually unilateral), dysphagia, fever, malaise and/or sore and bleeding gums, foul breath.

2. Examination revealed turgid papillae, bleeding easily, with ulceration and exudate. Usually one tonsil bore a grayish membrane which was readily detached, leaving a necrotic, foul smelling ulcer. The glands on the affected side were swollen and tender.

3. Smears from the gums or tonsil revealed innumerable spirochetes and fusiform bacilli. All smears were prepared according to the following routine: [7]

(*a*) The patient washed his mouth and gargled with a sodium bicarbonate solution.

(*b*) A cotton swab was applied to the infected area, removing the membrane and then discarded.

(*c*) A fresh swab was used to take the smear from the desired area.

(*d*) This swab was then rolled, not rubbed, over a crayon encircled area on a clean glass slide and stained with 2 per cent gentian violet solution.

4. Diphtheria bacilli were not identified on any smears. Leukemia and agranulocytic angina were excluded by blood examinations. Syphilis was ruled out by negative serologic reactions and also by the fact that Treponema pallidum is very fine and shaped like a corkscrew, while Spirillum vincenti is much coarser and has long undulating curves.

PLAN OF TREATMENT

All patients were treated with intramuscular injections of penicillin sodium in doses of either 10,000 or 20,000 units every two or three hours night and day until a total of 100,000 to 200,000 units had been given. Some patients were treated with penicillin only, some were given hydrogen peroxide mouth washes following penicillin, and still another group was observed in the dental clinic,[8] where tartar, caries and other pockets of infection were treated to establish proper drainage. All patients remained ambulatory during the therapy.

CRITERIA OF CURE

Patients in this study were retained under observation until smears on three successive days did not reveal the presence of spirochetes. They were then advised to return in seven days and again in fourteen days for clinical observation and bacterial studies. For academic purposes in several cases smears were taken night and day before each succeeding injection of penicillin. In many cases all spirochetes had disappeared from the slide after 70,000 units had been given and in no instance were spirochetes found after 100,000 units of sodium penicillin had been administered. All patients were symptom free within twenty-four hours after the first injection; that is, they were afebrile, were free from malaise and had no pain on swallowing. Usually the ulcerated area appeared much cleaner, and signs of epithelization were present. In the vast majority of cases the gums and tonsils became clinically well in forty-eight to ninety-six hours. Patients were judged as cured after becoming symptom free, after demonstrable clinical healing of ulcerations and after

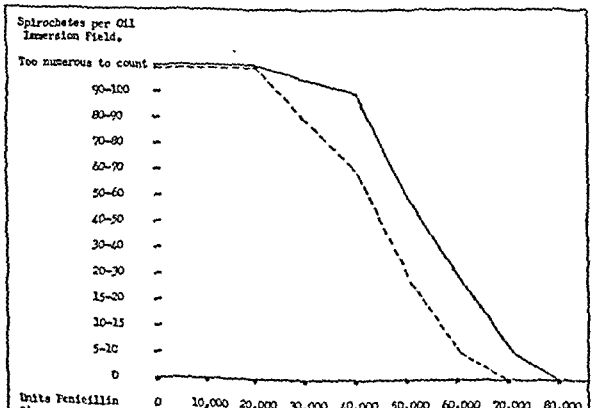
three negative smears were obtained, provided smears remained negative in the follow-up period of two weeks. Several patients whose smears were negative within the first twenty-four hours suffered relapses, and spirochetes were demonstrable in small numbers after forty-eight hours. All of these, however, responded to further penicillin administration. Patients who still had ulcerations but no demonstrable spirochetes after forty-eight hours were not given additional penicillin; but in these instances healing was complete in another twenty-four to forty-eight hours.



MATERIAL STUDIED

A total of 50 patients suffering from Vincent's angina or Vincent's stomatitis or both is included in this study. All were men between the ages of 18 and 35. The average duration of infection before the patient reported for treatment was five days. Only 3 of the patients had received any treatment prior to administration of penicillin sodium, and this without clinical or bacteriologic improvement. All patients studied fulfilled the diagnostic criteria previously enumerated.

RESULTS OF TREATMENT

The accompanying chart demonstrates the rate of disappearance of spirochetes from Vincent's ulcerations as penicillin was administered. Smears were taken in the manner described before each succeeding injection of the drug, and an effort was made to count the number of spirochetes per average oil immersion field. Owing to inability to spread the material evenly over all parts of the slide, many inaccuracies in the actual count have no doubt occurred; however, as the chart shows, the number of organisms diminished rapidly and in all instances spirochetes could not be demonstrated in any part of the slide after the eighth injection or 80,000 units of penicillin sodium. It was also demonstrated that the fusiform bacilli decreased in number in similar proportion, though not as rapidly.

In the table are shown the results of treatment in respect to the size of individual doses and the length

Rate of disappearance of spirochetes in Vincent's stomatitis (solid line) and Vincent's angina (broken line) after administration of penicillin.

of therapy and also in respect to use of penicillin alone as compared with the use of penicillin in conjunction with other procedures. The most satisfactory results were obtained as shown in column A. In this series 10,000 units was administered every two hours until 100,000 units had been given; this was followed by the use of 3 per cent hydrogen peroxide as a gargle four times daily for seventy-two hours in the cases of Vincent's angina, while in the cases of stomatitis the patients were referred to the dental clinic for correction of possible causative factors such as fillings, caries, malocclusions or gingival flaps. Ninety-five per cent of these patients in the first twenty-four hours obtained

negative smears which remained negative during the three week follow-up period. The remaining 5 per cent obtained a similar result when an additional hundred thousand units of penicillin was administered in the next twenty-four hours. All patients were symptom free after ten injections and remained ambulatory during treatment. Beginning epithelization could be observed of the ulcerations in gums and tonsils the first day, and the tissues appeared completely healed in all cases after ninety-six hours had elapsed. Column B reveals the results of treatment with penicillin alone; 81 per cent were cured in twenty-four hours and the remaining 19 per cent in seventy-two hours after an additional hundred thousand units. Column C demonstrates that 100,000 units given in divided doses of 20,000 units each with a three hour interval was much less satisfactory, with only 53 per cent obtaining a twenty-four hour cure. The remaining cases did, however, become negative when the therapy was repeated. The natural conclusion from these studies is that 10,000 units of penicillin, given every two hours up to a total of 100,000 units and followed by prompt elimination of adverse dental factors plus the use of an oxygenating gargle or mouth wash, will eliminate Vincent's spirochete from the mouth and pharynx and result in rapid healing of ulcerations and dramatic relief of symptoms occurring in this infection. However, this report is merely preliminary and it is obvious that more cases must be observed and over a longer period of time before the results may be regarded as conclusive.

COMMENT

From the foregoing results it is evident, or at least suggestive, that penicillin sodium is an effective agent in the treatment of fusospirochetal disease. Since we felt that the causative agent in this condition is the symbiotic action of the spirochete and the fusiform bacillus, which probably become pathogenic when the vitality of the tissues is impaired, it was believed that elimination of one of these organisms, namely Vincent's spirillum, was sufficient to produce favorable therapeutic results. For this reason studies were confined to the spirochete, and it was discovered that the destruction of this invader by penicillin sodium effected cures in all

cases studied even though a few fusiform bacilli persisted in the mouth or throat.

From the point of view of the time required for cure, penicillin sodium was distinctly superior to all other forms of therapy in fusospirochetosis. It has been our experience that older methods required daily care and observation for a minimum of ten days and usually much longer; with penicillin this was reduced to three days, the necessity of isolation was promptly eliminated, the relief of constitutional symptoms enabled the patient to resume his normal activities quickly and further observation was required only once a week for two or three weeks. The reduction of treatment time and the diminishing cost of penicillin indicate that this method of therapy is both practical and economical for general office use. The time of therapy and the cost involved will be no doubt even further curtailed when the use of penicillin in beeswax-peanut oil mixture or the like has been established and only one injection is required for a complete treatment.[9]

In this series 2 patients developed a generalized maculopapular erythematous eruption which subsided in twenty-four hours. No other toxic reactions to the drug were observed.

It has been well established that fusospirochetosis may involve the larynx, the eustachian tubes, the middle ear and the genitalia and may even result in pulmonary complications with bronchopneumonia or lung abscess. In this series of cases no involvement of these sites was observed, and it was felt that the absence of these complications was probably the result of the early institution of penicillin sodium as the therapeutic agent. In the vast majority of cases fusospirochetosis is not fatal or even serious, but the length of disability makes it an important factor in the health of an army or community and therefore its prompt eradication is highly desirous.

As a final comment, it cannot be emphasized too strenuously that satisfactory results in ulcerative stomatitis are dependent on adequate elimination of any significant dental pathologic condition. This is unnecessary in Vincent's angina.

CONCLUSION AND SUMMARY

1. Penicillin sodium was used in the treatment of a series of ambulatory patients with fusospirochetal infections.

2. The optimal total dosage in this type of infection was 100,000 Oxford units of penicillin administered intramuscularly.

3. Fusospirochetosis responded promptly to divided doses of 10,000 units each given at two hour intervals.

4. Complete alleviation of symptoms and eradication of the causative organisms were effected in twenty-four hours after the institution of therapy, thus reducing the infectious period and the total time of treatment to about one fourth of that formerly required.

5. Follow-up studies were accomplished at weekly intervals without clinical or bacteriologic evidence of recurrence.

6. The study reveals that this infection may be treated while the patients are ambulatory, with a material reduction of the time and cost involved, and without complications arising.

7. Masking of the development of early syphilis in fusospirochetal disease when treated with penicillin necessitates interval serologic studies.

8. Untoward reactions of any consequence to penicillin sodium were not encountered in this series.

9. It is apparent that the primary treatment of fusospirochetosis belongs within the realm of chemotherapy, and with the more general supply and distribution of penicillin these treatments may be utilized in office practice and in clinics.

NUTRITION IN PREGNANCY

CURTIS J. LUND, M.D.
MINNEAPOLIS

Few fields of medicine are moving forward as rapidly as the field of nutrition. Certainly few offer greater opportunity for scientific research and its application to the problems of nutrition and health. On the other hand, some aspects of this problem, like the death of Mark Twain, have been greatly exaggerated. Much of the exaggeration has come from those exploiting the vitamins, some from pseudoscientific food faddists and some from studies inadequately controlled with unwarranted emphasis placed on single case reports. These unfortunate exaggerations have stimulated the enthusiast and have provoked distrust in the conservative. These and other reasons make it fitting to review discriminately some of the facts and fallacies of nutrition as it concerns the pregnant woman.

Nutrition as a whole or in any of its parts cannot exceed the optimum, which was Pirquet's term for "the amount desirable under given circumstances." "Super adequacy" cannot exist, but superabundance does and it is useless, wasteful in times of want and sometimes harmful. Obesity is a manifestation of a harmful superabundance, usually of carbohydrates and fats. Excessive administration of iron is an example of waste, for it is not absorbed from the gastrointestinal tract and is directly eliminated in the feces.[1]

Our present standards for dietary essentials are those of the Food and Nutrition Board of the National Research Council.[2] They are our best available yardstick of nutrition. Roberts,[3] in a critical discussion of the accuracy of these standards [4] for normal nonpregnant women, considered the allowances as fairly satisfactory but noted that actual experimental evidence was far from complete. This criticism holds to an even greater extent for the pregnant woman.

Some substances, such as the mineral elements and nitrogen, have been studied quite carefully by determinations of metabolic balances. These are the accurate determinations of intake and output of a substance during a given period of time. Such studies cannot be directly extended to all dietary essentials because not all are excreted unchanged. At present the newer methods of assay for vitamins in the blood, urine, tissues and body fluids are crystallizing our knowledge concerning this phase of human nutrition. These methods have not been widely applied to the pregnant woman

except possibly for vitamin C and recently to a limited extent for vitamin A. Even less has been done with the vitamin B complex, vitamin D and vitamin E.

One sweeping criticism can be applied to all studies attempting to determine the dietary requirements during pregnancy. They fail to take into account the problem of storage. It is clear that the pregnant woman stores many substances to a degree beyond the requirements of herself and her fetus. This capacity for storage, possibly of phylogenic origin, creates a reserve for emergencies. If these emergencies fail to develop the excess is excreted during the puerperium. Water is an excellent example, as is nitrogen [5] and probably iron,[6] calcium,[5] vitamin A and others. For this and other reasons we must be very cautious in classifying the diet of any pregnant woman within narrow limits and hesitant to make dogmatic statements concerning minor deviations. Certainly pregnancy produces a nutritional strain and certainly the dietary needs of the expectant mother are more than those of any similarly healthy but nonpregnant woman. However, this yet unmeasured increased demand has given food faddists, entrepreneurs and others opportunity for unwarranted advice and advertising.

THE DIETARY REQUIREMENTS OF NORMAL PREGNANCY

It is not my purpose in this paper to discuss the frequency of dietary deficiencies or the various social, economic and educational factors involved. For a practicing physician the problem is the dietary needs of each patient. She is not to be treated according to the nutritional standards of any other person or groups of persons. She is an individual problem and it is the physician's duty to take a short, accurate dietary history and to see that he or some other qualified person explains to her the dietary problems of pregnancy. Table 1 lists most of the basic foods and the approximate amounts of dietary essentials supplied by each.

Calories.—The average pregnant woman requires about 2,500 calories per day during pregnancy.[4] Those doing heavy work require more, the sedentary and the obese require less. The foods listed in table 1 provide most of the essentials with the caloric content limited to approximately 2,000. Additional calories are readily obtained by increasing carbohydrates and fats. If for purposes of weight reduction the calories are limited to less than 2,000, dietary supplements of minerals and vitamins may become necessary depending on the foods deleted.

Protein.—There is no unanimity of opinion as to the needs for protein. All agree that needs are increased. To provide for a positive nitrogen balance Coons [7] advised 70 Gm. daily, Dieckmann and Swanson [8] 75 Gm., the National Research Council 85 Gm. and others as high as 100 to 120 Gm.[5] Whatever the exact figure may be does not alter the importance of providing an ample supply—at least one moderately large serving of meat daily and liver once each week. The type of protein must also be considered and half or more should be grade A, which is that of animal origin, such as meat, milk and eggs.[9] There is no place for restriction of proteins in pregnancy whether normal or complicated. Few physicians still advise such restriction, but many patients unless warned to the contrary will voluntarily do so, apparently because of the old popular notion that high protein diets favor development of eclampsia.

Calcium and Phosphorus.—The metabolism of calcium, phosphorus and vitamin D is so intimately linked as to require joint discussion. In spite of the extensive work of such investigators as Macy,[5] Coons,[7] Dieckmann,[10] Oberst and Plass [11] and others, we know, as Macy recently said,[12] "neither the most satisfactory level of calcium intake nor the optimal retention of calcium at any physiologic age or stage of man's development." Most of the workers mentioned agree that a negative calcium balance does not ordinarily occur if 1.5 Gm. of native calcium is ingested each day. This amount of calcium not only supplies fetal needs but also permits the mother to gain calcium during the entire gestation.

One quart of milk daily supplies 1.2 Gm., nearly the normal requirement; the slight remainder is readily available in other foods. There is no need for supplements of calcium. Many physicians also forget the well known fact that calcium salts differ in the amount of calcium yielded. To equal the calcium obtained from a quart of milk it would be necessary to take 8 Gm. of dicalcium phosphate or calcium lactate or about 12 Gm. of the gluconate salt.

Phosphorus need not concern us. It is a well known fact that the American diet is high in phosphorus, and sufficient amounts are obtained if calcium intake is adequate.

The amount of vitamin D necessary for adult mineral metabolism is not known.[13] The Nutrition Council[14] has empirically advised 500 to 800 units daily for pregnancy. Conclusive experimental evidence is not available at this time.

Iron.—A daily intake of 15 mg. of iron will produce a positive balance in most women.[14] Again it is possible to supply these needs by diet alone if the woman does not enter pregnancy with a deficiency. This is of considerable importance, for not a few women begin with an iron deficiency due to chronic blood loss in the presence of a low intake. Determination of hemoglobin level during early pregnancy is essential and gives a very rough estimate of the dietary state as concerns this element. Iron is a "one way substance"; after ingestion it will be absorbed and held or will be rejected and eliminated in the feces.[12] It is not excreted in appreciable amounts.[1] The pregnant woman absorbs iron in greater amounts than the nonpregnant one and builds up stores in hypertrophied muscles and other tissues which Coons[6] calls "rest iron." Fetal demands are insignificant until the last three months, and even during the last month of gestation the fetus takes but 6.6 mg. per day.[6] It is interesting to note that many iron deficiencies appear before the last trimester, which indicates that the deficiency has not been due to the parasitic action of the fetus.[15] It has been suggested[16] that the diminished or absent gastric hydrochloric acid commonly found in pregnancy may be a factor in the failure of absorption of iron even in the presence of adequate supplies. Further investigation of this problem is indicated.

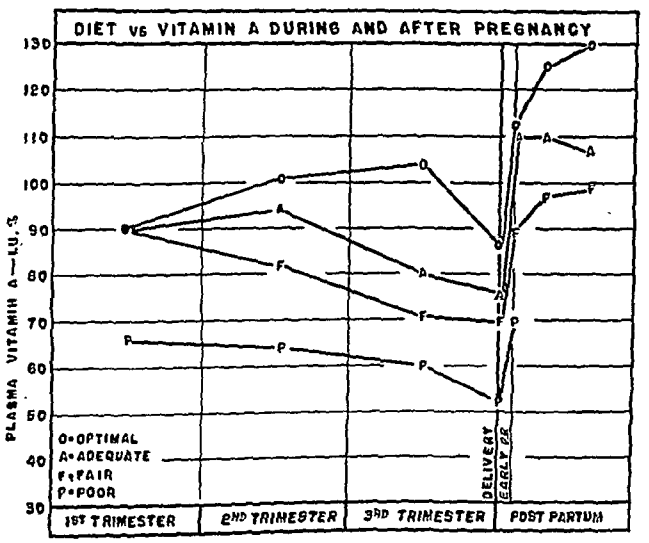

Chart 1.—Mean plasma vitamin A values of patients grouped according to diet. Note that the gestational decrease occurs in all, but the degree varies in regard to time and diet. All show the striking mobilization of vitamin A into the blood post partum.

Vitamin A.—Until recently little was known about the increased need for vitamin A during pregnancy. Within the past year several reports have appeared.[17] All have utilized the photocolorimetric methods of determination and all have recorded somewhat similar results. Interpretations of these data have been at some variance. Our study[18] of 212 women during pregnancy showed that plasma vitamin A values reflected in general the dietary intake of the vitamin. The difference between extremes of diet was great, but no patient with a poor diet had plasma values within the fully normal range for nonpregnant women. Seasonal changes in plasma vitamin A could not be demonstrated. The most definite changes occurred during the course of pregnancy and immediately after delivery. Our results showed, as did those of others,[19] that plasma levels tend to decrease during the course of pregnancy. We noted this in nearly every patient. However, the decrease was not always progressive nor did it appear at the same time in pregnancy. The time of appearance depended, at least in part, on the intake of the vitamin, coming early when the diet was poor and later when the diet was good. Chart 1 shows the relations of diet, vitamin A values and stage of pregnancy. Most striking of all was the immediate and unfailing postpartum elevation of plasma vitamin A. Within twelve to twenty-four hours after delivery every patient showed elevation of values. The average increase was roughly 33 per cent. The significance of these unusual changes is not known but affords interesting speculation. It appears to be another manifestation of maternal storage during pregnancy and release post partum for lactation or such emergencies as might arise. The gestational decrease cannot be due to fetal demands alone, for it occurred when 25,000 international units of vitamin A was taken daily, an obviously excessive amount. It was not due to hydremia of pregnancy, for the decrease was sometimes most pronounced during the last few weeks of pregnancy, when hydremia normally diminishes. Also concomitant determination of plasma carotene failed to show similar changes. Once elevated, plasma values were readily maintained at adequate levels during lactation. This suggests that vitamin A requirements are not greater during lactation, as has been previously believed.

Various estimates have placed requirements during pregnancy at from 6,000 to 8,000 international units daily. Until the problem of maternal storage is solved no one can say definitely what the needs of pregnancy are: a problem particularly significant as regards vitamin A, because it is fat soluble and readily stored. Our studies suggest that diet alone may not be sufficient during the last half of pregnancy; at least diet alone did not always maintain optimal plasma values. The addition of 5,000 international units of vitamin A during the second trimester and 10,000 international units during the third trimester provided ample amounts for the maintenance of best possible plasma levels.

Vitamin B Complex.—The importance of this group of water soluble substances cannot be denied. They are poorly stored, usually rapidly excreted and consequently

must be continually replaced. At least a dozen separate factors of the B complex have been described. Adult human requirements have been recently reviewed by Elvehjem,[20] but needs for pregnancy have not been established. The recent report of Lockhart [21] summarizes the literature as regards thiamine. She believes

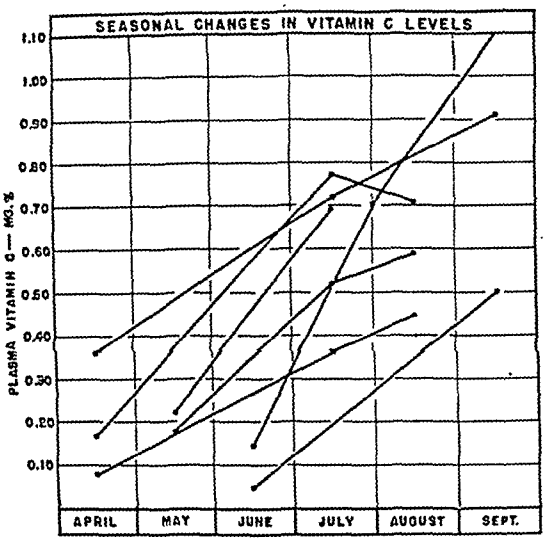

Chart 2.—Importance of season in relation to plasma vitamin C. For various reasons the diet of these women was poor in vitamin C during the winter but quickly improved when fresh fruits and vegetables were abundant.

that requirements may be three times those of nonpregnant women. A daily intake of 1.8 mg. is thought to be enough. Most of the natural supply comes from whole wheat cereals, enriched bread, pork and liver.

Need for riboflavin has been estimated to be 2.5 mg. daily, an amount not difficult to obtain from the diet alone. In fact, a quart of milk provides 2 mg., or nearly the minimal requirement. Liver, eggs and vegetables are the other reliable sources.

Niacin requirements are estimated at 18 mg. Liver, other meats and vegetables are the common sources.

The significance in human nutrition of the other members of the complex such as pantothenic acid, pyridoxine, biotin, choline, para-aminobenzoic acid, folic acid and others cannot be told. Undoubtedly each has its place in human economy. These and probably many as yet unrecognized factors occur for the most part in foodstuffs such as liver, meat, cereal grains, eggs and milk. In any event, adequate amounts of all can be supplied by diet alone and should be supplied in that manner if possible.

Vitamin C.—This too is a water soluble substance which is poorly stored and readily excreted. Daily requirements are constantly being revised upward for normal adults as well as for pregnant women. Earlier estimates for pregnancy of 75 to 100 mg. daily are probably too low. More recent ones range from 150 [4] to 200 [22] mg. daily. In a recent study [23] of 197 pregnant women we found a wide variation in plasma vitamin C levels, but in general the dietary intake was reflected in plasma values. The mean plasma value for 152 patients with an adequate diet was 0.95 mg. per hundred cubic centimeters, for 103 patients with a fair diet 0.52 mg. per hundred cubic centimeters and for 45 patients with a poor diet 0.18 mg. per hundred cubic centimeters. This study, which covered a two year period, showed that one of the greatest influences on the dietary intake of vitamin C was season. During the summer only 7 per cent of all our patients had a poor intake, while 63 per cent of the diets were completely adequate; during the remainder of the year 20 per cent were definitely inadequate and 43 per cent completely adequate. Chart 2 illustrates the ease with which a poor diet improves during the summer. This does not mean that adequate diets are not possible during the winter even in northern latitudes. Table 2 shows the plasma values for a group of 6 women who conceived in late summer and delivered in late spring. These women were intelligent and cooperative but had limited finances. Yet by the use of generous amounts of citrus fruits and at least one fresh vegetable each day they maintained excellent values for ascorbic acid through the entire winter.

While we made no attempt to study extensively the effects of supplements of ascorbic acid we did observe 24 women at delivery who, in addition to an "adequate" diet, had received 25 mg. of ascorbic acid daily for several months. The mean plasma value for these patients was 0.94 mg. per hundred cubic centimeters, while the value for 128 patients with adequate diet but without such supplements was 0.95 mg. per hundred cubic centimeters. Small doses of vitamin C are of little benefit to the person with a good diet and may lead the physician into a false sense of security concerning patients with low intakes unless he realizes that daily requirements are six to eight times greater than 25 mg.

Vitamin E.—The ubiquitous distribution of vitamin E, alpha-tochopherol, makes deficiency unlikely. It is found in grains, vegetables, eggs and meat. Requirements in pregnancy are unknown.

Vitamin K.—The pregnant woman rarely exhibits a deficiency of vitamin K, as it is freely synthesized in the gastrointestinal tract. It is common practice to administer 1 to 2 mg. of vitamin K during labor, not for maternal needs, but to build up fetal values for the critical early neonatal period. This is probably a justifiable practice but may not be necessary.[24]

TABLE 2.—*Individual Values of Six Patients Who Became Pregnant During Late Summer and Who Were Delivered in Late Spring*

Patient	Plasma Vitamin C in Milligrams per Hundred Cubic Centimeters			
	August, September	October, November, December	January, February, March	Delivery April, May
Mrs. Be.	1.01	0.77	1.00	1.10
Mrs. Ba.	....	0.99	1.05	0.99
Mrs. Jo.	....	1.22	1.15	1.23
Mrs. Ke.	1.01	1.22	1.23	1.36
Mrs. Ku.	0.85	1.05	0.81	0.73
Mrs. M.	....	1.30	1.00	1.36
Average	0.93	1.09	1.04	1.12

These excellent vitamin C levels were maintained through the winter by diet alone.

THE FETUS

Recent studies have not materially altered the older concept that the fetus is more or less a parasite and takes what nutriments it needs, sometimes at its mother's expense. This is well illustrated by weight, which cannot be influenced by maternal dietary restriction short of starvation. The general literature of fetal nutrition was summarized by Huggett [25] in 1941.

While it is true that the fetus obtains materials at maternal expense, it cannot obtain something that the mother does not have. Burke and her associates [26] have recently reported a high incidence of physically unfit infants born of mothers with poor and very poor food intake. Specific maternal deficiencies when severe may be exhibited by the newborn infant. For example, maternal deficiency of iron may lead to poor fetal storage and though the infant at birth has normal hemoglobin values it may develop an anemia during the first year of life.[27]

The placental transfer of vitamins is not completely understood, although evidence suggests that the fat soluble vitamin A differs greatly from the water soluble ascorbic acid. Our experimental findings, as well as a review of the recent literature,[28] indicate that plasma vitamin A values of the newborn infant are low, the range being about one-half those of the adult. Furthermore, we found that fetal values are completely independent of maternal values and could not be elevated even when the mother was given enormous doses (330,000 international units) of vitamin A daily before delivery. By contrast, carotene, the precursor of vitamin A, apparently passes the placenta regularly since fetal values, though only one-tenth as high, were usually directly related to those of the mother. From a prepared curve fetal values can be predicted with reasonable accuracy from known maternal values. Evidence that carotene was synthesized to vitamin A by the fetus was not apparent, for there was no correlation between fetal plasma carotene and vitamin A. This lack of correlation does not necessarily exclude the possibility for a similar situation exists in the adult.

Vitamin C behaved differently. Fetal values were always higher than maternal ones and in general the two were roughly correlated. It was most unusual to find values of the newborn infant in the deficiency range. The lowest value recorded by us was 0.10 mg. per hundred cubic centimeters (maternal value 0.0). Of the others 5 were between 0.25 and 0.60 mg. per hundred cubic centimeters, 17 were between 0.61 and 1.00 mg. per hundred cubic centimeters and the remaining 71 were all higher.

COMPLICATIONS OF PREGNANCY AND NUTRITIONAL DEFICIENCIES

It is becoming increasingly apparent that too much attention has been focused on the deficient diet as a cause of complications while too little attention has been given the nutritional deficiencies produced by the complications of pregnancy. As regards the former the problem may be considered in terms of general or specific dietary failure. Numerous reports have attempted to link diet with success or failure of gestation.[29] The recent report of Burke and her associates [26] suggests that complications of pregnancy and labor, the toxemias in particular, are common when diet is poor or very poor, and rare when diet is good or excellent. Ebbs, Tisdall and Scott [30] and the Interim Health Report of the British Isles [31] reported more toxemias, anemias and premature labors when the diet was deficient. Addition of certain food essentials decreased the incidence of these complications. More recently Dieckmann and his associates [15] found that the addition of calcium, phosphorus, iron and vitamins A and D to the diet did not change the course of pregnancy and labor. The reasons for such discrepancies are not clear now. Deficiency of a single food factor is rare; nevertheless we sometimes find certain characteristic clinical conditions associated with specific deficiencies.

Protein deficiencies are manifested in several ways. The two most common are nutritional edema and anemia.[32] Nutritional edema must be clearly differentiated from that of toxemia, and the anemia from that of iron deficiency or the primary anemia of pregnancy. It is also said [33] that ample dietary protein favors lactation. Therapy is simple: the ingestion of large amounts of meat.

Many reports have stressed the increased need for calcium during pregnancy and have reported relief of many symptoms from such therapy. It has been said [34] that administration of calcium and vitamin D reduced the incidence of toxemia, relieved muscular cramps, reduced blood loss and helped preserve the teeth. Dieckmann and his associates,[35] in a critical review of some of these claims, presented evidence that administration of calcium was without significant effect on blood loss, duration of labor, incidence of toxemia or premature labor. It is exceedingly difficult to reconcile some of the glowing clinical reports with physiologic facts, and until additional evidence appears we must assume that the pregnant woman in this country very rarely exhibits calcium deficiency. Certainly it has been definitely proved that pregnancy cannot withdraw calcium once laid down in tooth enamel.

A deficiency of iron leads directly to anemia, which is easily recognized and treated. Administration of 15 grains (1 Gm.) of ferrous iron daily will suffice in most instances.

Complications of pregnancy due to deficiency of the fat soluble vitamins A and D are difficult to prove. Because of storage, depletion develops slowly. Very little is known of vitamin D in the adult or in the pregnant woman. In our study of vitamin A we found no specific complications associated with low plasma values. In fact, very low plasma values were not

common. There was no correlation between low values and the toxemia of pregnancy, as might be expected on the basis of liver damage. There was no correlation with anemia of pregnancy, although this has been described.[36] We did note slightly less puerperal morbidity in mothers with highest values While this could be a specific effect, it is unlikely and probably reflects the salubrious effect of a generally good diet, good antepartum care and a cooperative patient

The water soluble vitamins B and C are probably of greater importance to the health of the pregnant woman than any of the others, but it is difficult to avoid the familiar fallacy of *post hoc ergo propter hoc* in dealing with these vitamins For that reason I shall review briefly some of the complications of pregnancy associated with deficiencies of the water soluble vitamins

Regardless of cause, prolonged and severe vomiting of pregnancy produces starvation. Aside from fluids and electrolytes, one of the earliest deficiencies is in vitamins B and C. A vicious cycle may be set up by the administration of glucose parenterally, for the metab-

TABLE 3—*Plasma Vitamin C Values in 241 Women with No Acute Infections During Pregnancy in 24 Women Before Onset of Acute Infection and in 35 Women After Acute Infection*

Controls, no infection	241	0 73	±0 242	0 00414	0 61
Before acute infection	24	0 66	±0 364	0 0552	
After acute infection .	35	0 40	±0 286	0 0234	0 015

Note the significant lowering of values after infection
* P indicates the probability of the magnitude of difference of means being exceeded solely through errors of random sampling

olism of glucose requires thiamine hydrochloride. The sudden exhibition of ample amounts of glucose quickly uses any remaining thiamine, thus precipitating an even greater deficiency. The grade of the deficiency depends on the duration and severity of the emesis. All grades occur. Occasionally we have seen such severe manifestations as polyneuritis, Korsakoff's psychosis, beriberi heart disease, severe glossitis and even pharyngitis. We have also observed plasma vitamin C depleted to zero with clinical manifestations of scurvy.

In 3 cases of severe hyperemesis gravidarum, retinal hemorrhages were noted. Administration of large doses of vitamin C parenterally (1,000 to 15,000 mg.) prevented formation of new hemorrhages For this reason I believe that at least some, if not all, of the retinal hemorrhages seen in this disease may be due to increased capillary fragility induced by the lack of ascorbic acid. In none of these 3 patients was the pregnancy interrupted, and all recovered.

The therapeutic requirements of these vitamins depend on the severity of the disease. As a general rule the daily dosages range as follows thiamine 5-10 mg., riboflavin 5-10 mg., niacinamide 50-200 mg., pantothenic acid 5-25 (?) mg., pyridoxine 5-25 (?) mg. and ascorbic acid 500-1,000 mg. It must be clearly understood that such vitamin therapy is but a part of the usual regimen of therapy commonly employed.

Infections may quickly deplete the water soluble vitamins. Chart 3 illustrates plasma vitamin C in pyelitis of pregnancy and chart 4 the effect of a breast abscess. These reactions are typical of any acute infection. The physician must be on guard at these times and supply supplements, particularly if the dietary intake is poor.

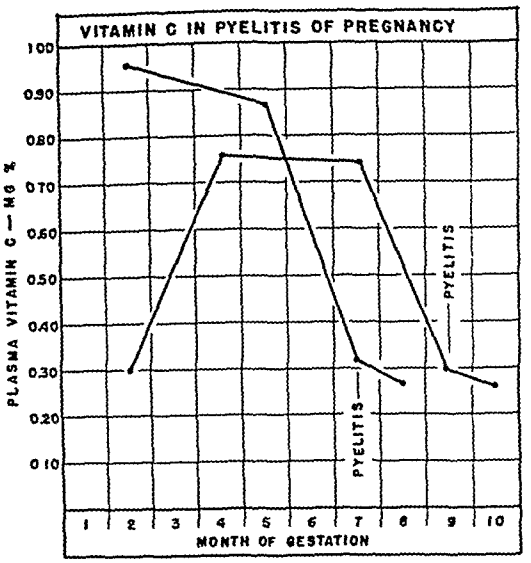

Chart 3.—Pyelitis of pregnancy, like any acute infection, may quickly deplete vitamin C, as these 2 cases illustrate.

While vitamin C diminished after infections, we could not demonstrate that low plasma values influenced the development of infection (table 3).

Certain other complications may occasionally arise from vitamin deficiencies. For example, we observed a peculiar type of postpartum hemorrhage (bleeding in

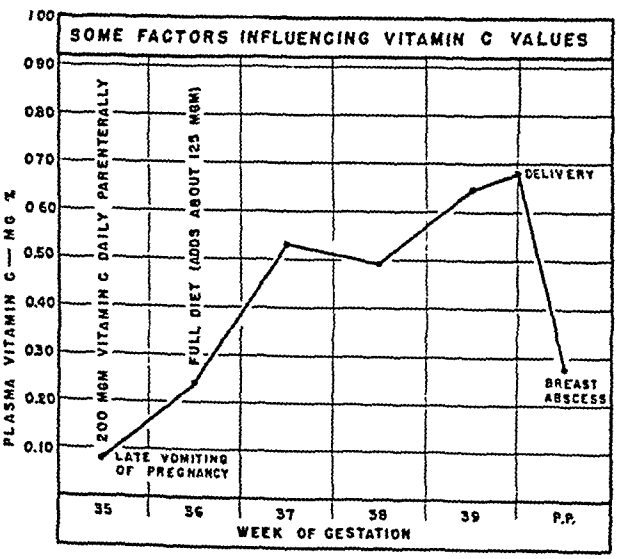

Chart 4.—Because of late vomiting of pregnancy this woman had a low plasma vitamin C. Fairly large amounts (325 mg. daily) slowly elevated her plasma level but failed completely to maintain that level after acute infection

small but constant amounts from the uterus for twenty-four hours ater delivery). This woman's plasma vitamin C was zero, and no other cause for the bleeding was found after a careful search. Administration of 1,000 mg. of ascorbic acid was followed by cessation of the bleeding.

These and many other unusual and fascinating stories of isolated instances of vitamin deficiencies are of minor clinical importance by virtue of their rarity and should not be stressed, for they no doubt contribute to some of the unjustified publicity of nutritional deficiencies.

SUMMARY

It is clear that the normally healthy, pregnant woman requires more dietary essentials than the similar nonpregnant woman. The exact extent of this increase is not known for any substance, but approximate values have been reasonably well established. Under ordinary conditions these needs can and should be met by diet alone. For optimal supply the daily diet should consist of one generous serving of meat, including liver weekly, a quart of milk, an ounce of butter, one fresh vegetable, one green leafy vegetable and one other cooked vegetable, generous amounts of citrus fruits or their equivalent, an egg and whole grain cereal or enriched bread. Beyond this, supplements are unnecessary except possibly 5,000 international units of vitamin A during the second trimester and 10,000 international units during the last trimester. Administration of vitamin K to the mother in labor or to the newly born infant is probably justified.

Gross deficiencies of diet undoubtedly influence unfavorably the course of pregnancy and the health of the newborn infant. An excellent diet favors a successful course and termination of pregnancy for mother and infant. Lesser degrees of deficiency are not easily diagnosed, nor is their significance understood.

Complications of pregnancy probably exert a greater influence on nutrition than does nutrition on them. Such conditions as hyperemesis gravidarum, pyelitis of pregnancy and puerperal infection and other acute and chronic infections may produce nutritional deficiencies. These are conditions which frequently require dietary supplements, sometimes in large amounts.

ABSTRACT OF DISCUSSION

DR. FRED L. ADAIR, Chicago: We must recognize that physicians are really the health educators of the community and we should be certain that when we educate our patients they are being educated soundly; otherwise we may have to uneducate them later. We have to recognize certain facts about foods: First, that there are no standards which apply to all foods; second, that there are no standards which apply to all individuals. Consequently we have to adapt the food to the individual. Foods are both quantitative and qualitative, and no food could be produced which contains anything which is not present in the environment in which it is grown. Individuals also are creatures of their environment. Not only the quantity of food but also its quality is subject to variation and there are environmental and seasonal variations of food. Our civilization has had foisted on us a lot of artificial foods. Fresh and natural foods are altered by the various processes which have adapted them to our civilization. The effort to enrich flour and bread is a result of a deprivation of our flour and bread of certain essential things which are in the whole grains. This is particularly noticeable, I think, with reference to flour and corn meal. The efforts at the enrichment of corn meal have not as yet been successful. The effort is necessary on account of the mores of the people. People like white bread. Most of them prefer white bread to whole grain bread. Proteins are closely "tied in" not only with nutrition but also with immunity. Proteins not only have certain nutritive values but also have very definite protective values in the resistance to infection. The proteins of highest quality, from the standpoint both of nutritive value and of their protective qualities, seem to occur in meat, in milk and in eggs. They have certain superiorities over proteins which are derived from grains. The minerals, of course, vary in importance, but there are special reasons for the addition of these to the diet. The pregnant woman has to store not only for herself but also for the growing fetus. Added to her actual maintenance needs are the requirements which are immediate for the fetus and also the storage needs of the mother, to supply her in the period subsequent to delivery and the period of lactation. Certain elements in her diet are required for storage for the fetus, which is another problem about which we have even less information than we have on the storage for the individual. The first trimester of pregnancy often presents great difficulty not only to meet the maintenance requirements of the individual but to provide for storage of the essential things which the fetus needs mostly in its later period of development. Probably most of these requirements have to be met in the second trimester of pregnancy after some of the anorexia, nausea and vomiting of the early period of pregnancy disappears.

THE PROBLEM OF NONFLUORESCENT RINGWORM OF THE SCALP

A WARNING

OSCAR L. LEVIN, M.D.
AND
HOWARD T. BEHRMAN, M.D.
NEW YORK

The presence of an epidemic of ringworm of the scalp in New York has been known for several years. During this period new cases have appeared sporadically throughout the United States and have produced minor epidemics in various cities. In a previous publication we [1] discussed the routine diagnosis and treatment of epidemic tinea capitis. In the majority of instances the infection is due to either "animal" (Microsporum lanosum) or "human" (Microsporum audouini) types of fungi. While these agents are responsible for different clinical and laboratory findings, they have one important property in common. This peculiarity is disclosed by examination of the infected hairs by means of Wood's light or filter. This light or filter is composed of glass containing sodium barium silicate and nickel oxide. When placed over a source of ultraviolet radiation it screens out all wavelengths except those in the near portion of the ultraviolet part of the spectrum (3,600 angstroms). These rays impart a fluorescence to hairs infected with members of the microsporum group and, to a lesser degree, to hairs infected with Achorion schoenleini (favus). The infected hairs appear as short, luminous, bright yellowish green stubs. As a result of this observation, filtered ultraviolet rays have been employed in various institutions such as hospitals, schools and orphan asylums for the purpose of case finding. These "screening" procedures have been and will continue to be of great value in the detection of both early and advanced cases as well as in the determination of cure. Unfortunately, this device has occasionally been employed by those not thoroughly acquainted with the mycologic background of tinea capitis. In several instances these individuals have informed the patient or the family that there is no evidence of ringworm of the scalp because Wood's light failed to disclose fluorescence. This may be true in proved cases of treated Microsporum infection, in which two negative examinations at intervals of three weeks suffice for discharge of the patient. However, it is of the utmost importance that information be dis-

From the Department of Dermatology of the Mount Sinai Hospital.

seminated to the effect that a small percentage of other fungous infections of the scalp do not produce fluorescence under the filtered ultraviolet rays. It is fortunate, indeed, that this proportion is usually less than 10 per cent during an epidemic, but it may increase considerably if the infected child is allowed to remain in school because of an incorrect diagnosis. In addition, the organisms producing these nonfluorescent infections are vastly more recalcitrant to therapy. The following case is illustrative of the entire problem, as this child was permitted to attend school for several months after the development of the fungous infection of the scalp.

REPORT OF CASE

History.—D. Z., a white boy aged 7 years, first seen on Nov. 6, 1943 in the Dermatologic Clinic of the Mount Sinai Hospital, was said by his mother to have had "sores" in his head for a number of months. The school authorities had been uneasy about the condition, but repeated examinations under the Wood's light failed to disclose the classic greenish fluorescence of Microsporum infections. Accordingly the child continued to attend school during this entire period. The first examination of the scalp in the clinic showed several crusted, follicular papules irregularly disseminated throughout the hair. A few pea to dime size (18 mm.) erythematous, eczematoid patches were also in evidence on the scalp and the back of the neck.

Laboratory Examinations.—The child was first examined under the Wood's filter. At the time of this examination the scalp was completely covered with an ointment, so that proper study was impossible. The mother was advised to shampoo the scalp daily and to return for further examination. At the subsequent examination, rapid perusal of the scalp during a busy clinical session with numerous classic cases of Microsporum infection failed to disclose any abnormalities under Wood's light. Routine examination of several extracted hairs showed no trace of fungous infection. Cultures were performed with other hairs as a routine measure. Within a short time one of the culture plates began to show an unusual type of fungous growth. The child was recalled for further study. At this time careful examination of the scalp under Wood's filter brought to light a dull white fluorescence of a number of scattered hairs, especially over the occipital and temporal regions. These hairs were extracted and examined microscopically. They exhibited large spores in chains in the shaft of the infected hairs.

Cultures were made of the abnormal material. Within ten to fourteen days they began to show a velvety tan surface. The central portion of the colony was lower than the rest of the surface. The margin of this central area fell away sharply to form a crater-like border. Culture mounts showed numerous microconidia occurring *en grappes* and as thyrsi sporiferi.

The diagnosis of Trichophyton crateriforme infection of the scalp was made and confirmed on numerous occasions subsequently. Roentgen epilation was advised as the only possible method of cure of the fungous infection of the scalp.

COMMENT

There are various types of fungi responsible for infection of the scalp. The offending agents responsible for the widespread epidemic of ringworm of the scalp in the United States fall into two main groups for the purpose of classification.

The first group, and the less important of the two, is that due to the so-called "animal" type of fungus. In this group, the causative organism is Microsporum lanosum. This organism is usually transmitted to children by infected cats or dogs. Clinically the disease appears as one or several scaling, inflammatory patches in the scalp. In this scaly patch there are found pustules, or groups of pustules, around the hair follicles, as well as broken-off hairs. Similar lesions may be present elsewhere on the body. The hairs can be removed with ease from the infected sites. Microscopic examination of these hairs furnishes a rapid diagnosis, as evidenced by the presence of a mosaic sheath of spores around the hair shaft. Further confirmatory aids in establishing a diagnosis include trichophytin tests and cultural studies. Trichophytin is an extract of fungi isolated from patients with ringworm. Owing to the inflammatory reaction produced by the "animal" ringworm, immunologic phenomena are elicited as evidenced by a positive trichophytin reaction. Cultural studies on special mediums (Sabouraud) show dull tan colonies with a lemon yellow substratum within five to seven days. Examination of the infected hairs or scalp by means of Wood's light is corroborative of the diagnosis. These rays impart a fluorescence to hairs infected with the Microsporum group. The infected hairs appear as short luminous, yellowish green stubs.

The second group of fungi etiologically responsible for tinea capitis is composed of the so-called "human" type of organism. The present epidemic is composed mainly of cases due to this organism, namely Microsporum audouini. The disease is spread from one child to another by means of direct contact. It may also be communicated by means of intermediate agents such as incompletely sterilized barbers' instruments, combs and brushes, hats, towels and the backs of chairs, especially theater seats. The lack of conscious effort on the part of parents of infected children to warn neighbors of the presence of the disease plays an important part in transmission of the infection. The clinical picture of the disease consists in the appearance of one or several small scaling patches on the scalp. These patches are composed of fine scales covered with brittle and broken hair stubs. The inflammatory reaction is slight, and pustulation is infrequently observed. The hairs are not easily extracted, owing to the ease with which they break following slight trauma. The unfortunate feature of this disease is the fact that the scalp may appear to be entirely normal from a clinical standpoint. In all suspicious or suspected cases, recourse must be had to examination by means of Wood's light. It is amazing to the novice to see an apparently normal and healthy scalp spring into focus as islands of greenish points under the filtered ultraviolet ray. Microscopic examination of the diseased hair is also corroborative of the diagnosis and resembles that seen with M. lanosum. The trichophytin reaction is usually negative, owing to the lack of inflammatory reaction produced by this organism. Cultural studies should be performed in all cases. In about seven to ten days there usually appears a grayish white fluffy culture with a central elevation. The substratum is usually reddish brown. In the culture mount the organism may be differentiated from M. lanosum by the rarity with which fuseaux (an asexual, oat-shaped spore) are found. Cultural mounts of M. lanosum, the "animal" type of ringworm, are characterized by the presence of numerous fuseaux.

In view of the frequency of infection due to the preceding fungi, the fact that other mycologic agents may also produce ringworm of the scalp has been overlooked. The remaining groups include less important members of the Microsporum family (Microsporum fulvum), Achorion schoenleini (favus) and the Trichophyton group. Infections due to M. fulvum resemble those produced by M. lanosum.

Achorion schoenleini, the cause of favus, produces a classic picture in the scalp. The lesions are sulfur yellow, cup shaped crusts with a characteristic mouse-

like odor. Occasionally the scalp merely shows irregular crusted areas or greasy scales. If the infection has been present for any length of time, areas of alopecia and scarring may be present. Under Wood's light the infected hairs fluoresce like the Microsporum group but are not as bright green. The cultural growth has a smooth, brownish, waxy surface. Splitting of the medium is common. Microscopic study of the culture shows the so-called favic chandeliers, which are diagnostic.

The Trichophyta are less well known than the preceding fungi and are more apt to be incorrectly diagnosed when they infect the scalp. They are roughly divided into endothrix and ectothrix groups, depending on their predilection for the hair shaft itself (endothrix) or the surface sheath (ectothrix). The three most important fungi in the endothrix group are Trichophyton violaceum, Trichophyton sulfureum and Trichophyton crateriforme. Infections caused by T. violaceum are known as "black dot" ringworm. This name stems from its peculiar appearance as patches of black specks through the scalp. These black specks are, in reality, broken hairs which have split off close to the scalp. In the other two endothrix infections, as well as in some of those due to T. violaceum, follicular pustules and small, eczematous, impetiginized patches constitute the usual clinical picture. Microscopic examination of the hairs reveals large spores, usually in chains, throughout the hair shaft. Cultures distinguish the various types and their variants. Under Wood's light the infected hairs show a dull white fluorescence. Exceptionally the hairs exhibit a bright, shining white fluorescence. This unusual fluorescence is apt to be overlooked in rapid or casual examinations. To the untrained it may be dismissed as of no consequence or as a phenomenon due to an applied ointment. Various salves and ointments do produce a white or bluish white fluorescence. However, this shine is not confined to individual hairs but is widely dispersed over irregular areas. In addition, fluorescence due to an ointment may be removed by scrubbing the area with alcohol or one of the fat solvents (acetone, carbon tetrachloride or the like).

The ectothrix Trichophyta are uncommon invaders of the scalp. The two important members of this group are Trichophyton gypseum and T. purpureum. They both have several variant types which are probably derivatives or subgroups. When T. gypseum involves the scalp it usually produces an inflammatory pustular infection.[2] In some cases this may be so severe as to form a boggy, pustular, almost carbuncular mass, usually referred to as a kerion. The infected hairs exhibit chains of spores external to the hair shaft. Cultures made from this material usually show snowy white, fluffy or powdery colonies. Under Wood's light the infected hairs appear normal. This important fact must not be overlooked—the infections produced by this group of Trichophyta supposedly do not impart fluorescence to the diseased hair. The clinical appearance may resemble that of M. lanosum, but the lack of fluorescence should lead the observer to further investigation. The diagnosis is a laboratory procedure and, if correctly performed, will clarify the problem. The other ectothrix of importance, namely T. purpureum, rarely involves the scalp, although we have encountered 2 instances of tinea of the beard due to this organism. The clinical appearance of cutaneous infections due to T. purpureum is usually that of a sharply marginated, dull red, eczematous patch. The cultural features are diagnostic, owing to the development of a purplish red color in the colony. Under Wood's filter this fungus has been reported as producing no fluorescence. As we have never seen a case of T. purpureum involvement of the scalp we cannot refute this observation. However, in both cases of T. purpureum infection of the bearded region there was a distinct white fluorescence of the infected hairs. For the sake of completeness, another member of the Trichophyta should be mentioned, namely Trichophyton niveum. It is a very uncommon cause of tinea capitis and resembles T. gypseum clinically and mycologically.

CONCLUSIONS

It should be emphasized that not all fungous infections of the scalp impart a noticeable fluorescence to the diseased hairs.

All patients suspected of ringworm of the scalp should be carefully studied before the diagnosis is discarded. A negative examination under Wood's light is not sufficient to exclude these cases. In every instance of clinically suspected infection the performance of microscopic and cultural examinations is essential.

The public health aspect of this problem is of extreme importance and must not be overlooked. These children should be reported to the local health authorities in order to insure adequate case finding and supervision of therapy. They should not be permitted to attend school or enter into close contact with other children.

GASTROINTESTINAL CONDITIONS

SIMULATING OR AGGRAVATING CARDIOVASCULAR DISEASE

WILLIAM EARL CLARK, M.D.
WASHINGTON, D. C.

The relationship of gastrointestinal disorders to cardiovascular disease is an old problem, and much has been written in regard to the confusion of symptoms. Dr. Paul White in the Alvarez Lecture before the Gastro-Enterological Association in 1937 spoke of "the differential diagnosis being of never ceasing importance and interest." He in turn quoted from Liddell and Scott's Greek Lexicon, giving the following definitions: "Kardia, heart, stomach" and "Kardiakos, of the heart or stomach, dyspepsia." He goes on to say "It is no wonder we have been confused ever since."

I have reviewed a great many cases from my practice in the last ten years and have endeavored to develop if possible some practical plan to separate those with some abnormality of the digestive system from those with actual cardiovascular disease. In many cases this can be done with a careful history and physical examination. In other cases it seems plain that the digestive difficulty and cardiovascular disease have occurred in the same individual, and the digestive difficulty is aggravating the cardiovascular disease. In a few cases even with the most careful history, physical examination, and with the aid of laboratory studies, including x-ray and electrocardiogram, it is impossible to be absolutely certain of the actual diagnosis.

Read before the Section on Miscellaneous Topics, Sessions for the General Practitioner, at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 15, 1944.

Pressure, burning or actual pain in the chest is a relatively common symptom, and it causes a patient to think of the possibility of heart disease. Since starting this paper I have read a most interesting article by Tinsley Harrison[1] on chest pain. When substernal pain occurs, especially pain related to effort or emotion, and lasts about sixty seconds, the great probability is that it is angina. Numerous observers have proved, however, that cardiospasm or irritability of the lower esophagus can give pain in the same location as actual angina pectoris. Chester Jones in his essay "Pain from the Digestive Tract" feels that pain impulses are associated with pressure or spasm of the musculature of the esophagus or cardia, and this pain may be referred over the same nerve pathway as angina. This is also true if a patient is having a gallstone attack. Some one said years ago that some of the most severe pain a human being can experience in this life is due to violent contractions of unstriped muscle.

Now the first group of cases that may be confused with cardiovascular disease are those of diaphragmatic or hiatus hernia. In the last fifteen years there have been an increasing number of diaphragmatic or hiatus hernia cases reported. Probably a large percentage of these cases may be without symptoms, but there are a certain number of these hernias that give symptoms that are quite suggestive of coronary disease. The fact too that hiatus hernia and coronary disease occur so often in the same age group tends to add to the confusion. In fact it is not unusual for the two conditions to occur together in the same individual. They also occur in the period of life when we so frequently encounter gallbladder disease, and it is well known how often cholecystitis and coronary disease occur in the same patient.

The most striking case I have found in the literature in which hiatus hernia resembled coronary disease is a case reported by William D. Reid in July 1940. A physician aged 52 complained of pain over the sternum and down the left arm, waking him at 3 a. m. He was seen by a cardiologist a few hours later. The pain was persistent and not completely abolished by two ¼ grain (16 mg.) doses of morphine. There was some referred pain noted over the inner aspect of both elbows and the little finger of each hand. It was worse on the left side, and the arm pain would last from one to three minutes at a time. The patient recognized little if any pressure symptoms and did not feel particularly ill. Gastric symptoms were entirely absent. During the subsequent four days he remained in bed. The white cell count remained normal, fever was absent and the electrocardiograms were normal. Examination of the heart itself gave normal findings. This substernal discomfort was located under the lower third of the sternum, where it persisted in a mild form. The patient was discharged at the end of four days as not having a cardiac infarction but with the suspicion that "something was wrong in the mechanics of the chest."

The patient did not feel well during the subsequent weeks. The aforementioned symptoms persisted in a mild form and occasionally in association with nervous tension. The patient reported a sensation similar to that felt when one has swallowed something too hot. Roentgen examination, which unfortunately did not include a search for hiatus hernia, disclosed nothing abnormal in the esophagus or gastrointestinal tract. A vacation of six weeks in Florida was prescribed. The patient was able to play golf, but there was only slight lessening of the thoracic and arm pain. Later he consulted an orthopedic surgeon who previously had successfully treated him for certain postural defects. The orthopedist thought that if the substernal pain was not due to heart disease it could be explained on the basis of muscular strain from faulty posture. Exercises were prescribed. These were faithfully followed from April until September without relief of the symptoms.

During this period that he was under the care of the orthopedist he had another rather severe attack of substernal pain, and a different cardiologist was called. After two days' study as a bed case again it was decided that cardiac infarction was not present. The symptoms at that time were believed to be partly orthopedic, partly cardiac and partly gastric in origin.

During the summer the patient resumed active exercise without untoward symptoms. The substernal and arm pains were present with increasing frequency. Finally it was noted that the pain was tending to center under the lower third of the sternum and that the feeling of discomfort after meals was becoming more frequent. He would get some relief by belching. A gastroenterologist was then consulted and he suggested hiatus hernia, and the hernia was demonstrated both fluoroscopically and on the x-ray plate. The establishment of the diagnosis was of decided value to the morale of the patient. Medical treatment for some months was of uncertain benefit. Finally the following year this patient consulted a surgeon. Radical cure by surgery was deemed unwarranted, and dilation of the esophagus was performed. There was a gradual abatement of symptoms to the date of writing, January 1940. Whatever symptoms occurred were minor and readily ignored.

A prominent physician in Washington has had a hiatus hernia for several years. When I questioned him as to why so many hernias were symptom free he ventured the following opinion, which I think is excellent: First there is a group with a short esophagus, where the cardiac end of the stomach is up in the chest and probably has always been up in the chest. These patients are very apt to be symptom free. In the second group the hiatus is large enough and free enough so that part of the stomach can herniate into the chest and return to below the diaphragm without getting caught. These too are apt to be symptom free. The cases that really give symptoms are the ones with a rather small hiatus so that when a portion of the stomach, even a small portion, herniates through the diaphragm it is more apt to get caught or even become incarcerated. In discussing his own case he states that if he had not known that he had hiatus hernia he would have thought he had angina, although in his case the pain does not come after exercise. In fact, exercise as a rule gives him some relief. Anything that upsets him emotionally, however, always brings on an attack of substernal pain. He has recently gone to the Mayo Clinic, where he had the phrenic nerves crushed, with complete relief of his symptoms although of course this has not cured the hernia.

Dr. Chester Jones has collected 128 cases of hiatus hernia from his own practice and from his service at the Massachusetts General Hospital. He found that the

1. Harrison, T. R.: Clinical Aspects of Pain in the Chest, Am. J. M. Sc. 207: 501 (May) 1944.

intake of food, especially a large meal, initiated substernal pain in 15 out of 25 cases, and half of these were shoulder and arm pain. Rather less frequently the act of lying down initiated symptoms of substernal pressure. He found that glyceryl trinitrate gave some relief, but it was not the prompt and characteristic relief that is obtained in angina. Belladonna or other antispasmodics gave relief to the pressure in the chest in 17 out of 18 cases. Belching gave temporary relief. In these 128 cases collected by Dr. Jones, 11 were heart disease and in 9 of these there was substernal pain with or without radiation. In all the latter there were small hernias, and Jones stresses that it was the patients with small hernias that had symptoms most nearly mimicking angina pectoris. Although exertion frequently precipitated substernal pain in patients with hernia, it was not as consistently so as in patients with real coronary disease. Dietary indiscretions and nervous tension were the most frequent precipitating causes of an attack of chest pain.

There is 1 remarkable case in my own practice that I have been looking after for the last two years. Mrs. L. M. C., aged 50, was referred by Dr. Howard Smith of Washington. Her past history was negative. She had been an unusually healthy, vigorous woman. Nine years ago she sustained a fall down ten steps, resulting in concussion. This fall occurred in June, and as near as she can remember around October of that year she began to have pain in the chest, referred to her shoulder and back and down her left arm. The pain was usually related to eating and she described it as being sharp, cutting off her breath. It was accompanied by heart consciousness and palpitation. She would get relief by the application of heat and by massaging between her shoulders. After a time she would explosively belch and be relieved. She was seen by a number of physicians, who diagnosed nervous indigestion following the shock from the fall. She was x-rayed on several occasions with negative findings. As the months passed, her symptoms increased in severity. Frequently if she was out socially to dinner she would have to excuse herself from the table and go somewhere to loosen her girdle, for she was "in agony" because of the pain in her chest referred to her back and arm. The pain never was referred into the forearm or fingers. Even though she had been x-rayed repeatedly, Dr. Smith had her x-rayed again and for the first time a diaphragmatic hernia was demonstrated.

She was treated palliatively for several months, but she grew worse. About Christmas 1939 apparently the hernia became incarcerated and she had to be taken to the hospital for observation and treatment. She developed a secondary anemia, requiring repeated transfusions. Finally she was operated on by Dr. Gwathmey and Dr. Rodman in Norfolk, Va. The opening into the diaphragm was so large that Dr. Gwathmey could put his hand up into the chest and hold up the heart while Dr. Rodman with difficulty pulled down the herniated stomach into its proper position. The large aperture of the diaphragm, which had evidently been caused at the time of the fall, was closed down to normal size. The stomach was very much congested and inflamed from the constriction and partial strangulation. Her convalescence was uneventful.

In 1940 she could eat anything, she regained her weight, and she was absolutely symptom free. In 1942 she developed a hernia in the operative wound. Dr. Smith operated and repaired this, and soon after she developed symptoms that suggested a recurrence of the hiatus hernia. This was verified with the x-ray, and it is interesting that when they put her in the Trendelenburg position to demonstrate the hernia there was such embarrassment of the heart that it caused her to lose consciousness. Whether from increased abdominal pressure from repair of the ventral hernia or whether the postoperative retching and vomiting caused a recurrence of the diaphragmatic hernia one cannot be sure. At any rate the stomach had again herniated through the diaphragm and the patient was desperately ill. She not only had substernal pressure and discomfort but became cyanosed if she made the least motion. On auscultation one could hear peristaltic gurgling over the precordia, just as one would elicit over the epigastrium.

I was called in on the case about this time and we did everything possible to give her relief by conservative medical management. We kept a Wangensteen tube in for days but apparently the hernia again was incarcerated, for the material drained away was brown coffee ground material, apparently from the ooze of the mucosa due to the constriction of the diaphragm. Again operation was decided on and she was got ready with transfusions, plasma and glucose. Dr. Howard Smith and Dr. Charles Stanley White operated and found almost the whole stomach, including the pylorus, up in the thoracic cavity. With considerable difficulty the stomach was pulled down, and as the patient was in such a weakened condition and bordering on shock no attempt was made to repair the hernia, but the stomach was stitched fast to the peritoneum of the anterior abdominal wall and the wound closed. By early afternoon the patient was better and she made steady improvement.

This past year they had to operate again and do an anastomosis between the duodenum and the upper jejunum, as there were adhesions around the ligament of Treitz that were causing obstruction, but since that time she has been relatively well, although she still has to avoid getting overtired and she follows a diet of the low residue type.

I do believe, especially in older patients, if they are somewhat obese, and if they have any atypical cardiac, respiratory or pressure symptoms under the lower sternum, that hiatus hernia should be thought of and an effort made to demonstrate or exclude such a condition. In general, patients with hiatus hernia associate the pain with eating, and too they are not apt to have symptoms when they are in the recumbent position at night. They may have symptoms after effort, as in true angina, but this is rare. Although our patient got relief by belching, in many of the patients with true hiatus hernia the gas and contents are incarcerated in the hernial sac and they cannot get relief by belching.

I would like to mention briefly a woman from Eastport, Me., who came to Washington to look after the home of her son and his two daughters of high school age. She was 73 years of age, and when we took her history we elicited substernal pain occurring after effort, referred down her arm. She also was able to differentiate another group of symptoms referred to the lower esophagus or cardiac end of the stomach which she related to eating. There was no question about her having coronary sclerosis with angina, her symptoms were so typical, and the electrocardiographic changes fitted in with that diagnosis. At the same time

she had distress high in the epigastrium and under the lower third of her sternum that was at times related to eating. X-ray examination showed the presence of a small hiatus hernia, so that this case illustrates the combination of coronary sclerosis, angina pectoris and hiatus hernia, with the aggravating influence of the hernia.

PATIENTS WITH CHEST PAIN

The next group of cases I want to mention is illustrated by a man of 69 who has been the chief in one of our government departments for years. He has been a sound, practical, effective administrator of his department. Gradually as he has grown older and as new conditions have come up, especially since the war, there has been a reorganization of his department. He does not seem to have the elasticity to meet the change. He comes into conflict with what he terms theoretical, unpractical and visionary younger men in his department. After a varying number of conflicts he goes to pieces nervously and develops a queer pressure in the upper left quadrant, referred into his left chest and into his neck. He does not relate the attacks to anything he has eaten and they are not related to effort, although they often waken him at 2 or 3 a. m. He thinks the symptoms are due to gas that traps or pockets under the diaphragm, causing the chest and neck pain. Naturally, like any one with chest symptoms he fears that his heart may be involved. To make the case a bit more confused, in the course of giving his history he described two attacks that sounded very much like real angina pectoris. These two attacks were associated with effort, and effort rather soon after meals.

His first electrocardiogram showed flattening of the T waves, enough to suggest a certain amount of coronary disease. I feel, however, that it is this emotional stress due to his inability to cope with changing conditions in his office, or, if I must be plain, it is the New Deal that seemed to be causing most of his symptoms. As he is almost 70 and eligible for retirement, I encouraged him to retire. He has enough normal interests to entertain him and he gladly accepted this advice. I put him on a program of lessened activity without stressing his possible coronary disease, and the relief from conflict and peace in his heart have allayed most of his symptoms. A second electrocardiogram was essentially normal.

There are many patients of highly nervous organization that may mention chest pain as one of their chief symptoms. They do not as a rule describe the pain as substernal pressure but more often at the outer border of the heart or in the chest wall. They will speak of it as a burning or pinching or they will have difficulty in describing it at all, like most patients with somatic sensations. Of course nervous or psychoneurotic patients also are more subject to irregularities, cardiac palpitation and so on; but usually by taking a careful history and doing a physical examination, with possibly an electrocardiogram, one can rule out cardiovascular disease. I was interested in talking recently with a friend who had returned from the meeting of the College of Physicians in Boston. He said he heard Dr. Paul White make the statement that cardiology had got top heavy and that the best trained men were getting back to the good old principles of a careful painstaking history and physical examination, and they put laboratory tests and electrocardiograms well down on the list in importance.

PATIENTS WITH CHOLECYSTITIS

Another group of cases I would like to mention that may simulate or aggravate cardiovascular disease are those in which there is cholecystitis or cholelithiasis. Over and over again the association of gallbladder disease and coronary sclerosis has been demonstrated. It is almost equally well known that a diseased gallbladder will often have what has been termed a trigger mechanism, initiating attacks of angina. I am not suggesting a cholecystectomy on every patient who has angina and cholecystitis, but if the patient is in relatively good condition and has gallstones, cholecystectomy will not only relieve the gallbladder symptoms but often will have a most favorable effect on the heart symptoms. I think that in the past we have been too prone to allow a patient to continue with what have been called silent or innocent gallstones. Dr. Lahey, Dr. Jordan and many other authorities have shown with what frequency these patients who were relatively good risks in their late forties or early fifties develop very definite symptoms related to their gallbladder when they are in their sixties and when they have become very questionable surgical risks. All of us have a certain number of such patients under our care. I know one in particular that I wish could have had cholecystectomy years ago, for the diseased gallbladder is now having an almost constantly aggravating effect on her cardiovascular disease.

NERVOUS EXECUTIVES

There is still another group of patients that I feel should be mentioned in this discussion of indigestion simulating cardiovascular disease. We are seeing a great many executives that are driving hard in their work, with too little recreation and rest. In many instances they are overweight and they are nervously smoking twenty, thirty or even forty cigarets a day. They begin to complain of gaseous indigestion and discomfort in the epigastrium, frequently referred into the chest. Often because they have got so little exercise and are overweight and tired they will be rather short of breath on exertion. In my experience most of these patients fail to have pressure or pain after exertion but may complain of atypical sensations like dragging or pulling in the left chest anteriorly, and they are always worse when under increased emotional strain. The Graham test may be negative, and the gastrointestinal x-ray examination will be negative except for irritability or spasticity. As some one describing this group of cases says, they have mild traffic jams along their gastrointestinal tract, especially at the cardia or pylorus, from spasm of the sphincters in these areas. Many of them will describe a burning in the epigastrium and over the course of the esophagus. Cutting out or drastically reducing their tobacco, and cutting down their schedule, usually brings about relief. I cannot sufficiently emphasize the relief there is to the mind of such patients if they can be reassured and given a sense of security that their heart is intact and that their symptoms are due to the strain they are under plus the tobacco.

SUMMARY

1. Diaphragmatic or hiatus hernia may present a clinical picture that resembles heart disease, especially coronary sclerosis with angina. And too it is the smaller hernias that are often overlooked that are most apt to give symptoms like those of cardiovascular disease.

2. The symptoms in hiatus hernia are much more apt to be associated with eating rather than with effort.

The pain is less promptly relieved with glyceryl trinitrate. Belladonna and phenobarbital, "Trasentin" or other antispasmodics usually relieve or modify the pain.

3. Gallbladder disease, especially cholecystitis with stones, is not only frequently found associated with coronary disease but may reflexly initiate attacks of angina. In properly selected cases cholecystectomy may lessen or even clear up the attacks of angina for a time at least.

4. Functional derangement of digestion and irritable colon syndrome may also mimic or accent cardiovascular symptoms.

1835 Eye Street N.W.

ABSTRACT OF DISCUSSION

DR. SARA M. JORDAN, Boston: I have found in many cases that even the large, long esophagus type of hernia, the hernia in which the stomach is almost completely upside down in the thorax, can be controlled by a careful regimen. On the question of other causes, perhaps less frequently encountered but still occasionally found in the gastrointestinal tract, which might confuse the picture and make one think of heart disease, it must be remembered that spasm at the cardia is sometimes initiated by pain only. Not only is there dysphagia from cardiac spasm but there may be simple, severe pain with the onset of the attack, which makes one think of coronary disease. A rapid fluoroscopy of the esophagus will settle the diagnosis there. Spasm in the pylorus may produce chest pain which radiates to the neck, the teeth and even down in the arms. Spasm in the sphincter of Oddi after cholecystectomy may also produce this type of pain. The diaphragmatic flexure, in my experience, more than any other condition has been a source of confusion in the diagnosis when patients have been sent with a question of coronary or gastrointestinal disease. Pocketing of gas in the high splenic flexure in an atonic colon directly under the diaphragm certainly may be the cause of substernal pain which radiates to the neck and arms and can be alleviated and prevented, of course, by gastrointestinal management. I have often had patients who come with high upper gastric or chest pain which is due entirely to a habit of belching. They don't always swallow air, so it really isn't aerophagia. Fluoroscopy of their stomachs does not reveal air. But watch the patient who has that type of pain and ask him if he has the habit of belching. Put him on a careful regimen, a little antispasmodic treatment, and ask him to be careful not to belch, and sometimes cure will ensue within a few days. A digestive tract upset in a cardiac condition is certainly not helpful; it is harmful. The attention to food, prescription of an easily digestible diet (it doesn't have to be too restricted, but the notoriously indigestible foods should be removed), attention to smoking and to the abuse of laxatives—all those things should be watched carefully in a cardiac patient in order to have the digestive tract help rather than hinder the condition.

DR. WILLIAM EARL CLARK, Washington, D. C.: I stated that as a rule large hernias are less apt to get caught, but Dr. Jordan brings out the fact that they sometimes do get caught, and 1 of the cases on numerous occasions became incarcerated. I agree also that some patients with a congenital short esophagus do have symptoms.

Public Acceptance of Medical Science.—Men who saw malaria driven out of Guadalcanal, and typhus beaten at Naples, will be very willing to accept the guidance of a profession that uses both stethoscope and microscope, combining sound practice with sound theory based on experiment. There need be no fear, in our time, of any danger from outside to public acceptance of medical art and science.—Corner, George W.: The Gifts of the Good Physician, University of Rochester, N. Y., 1944.

Clinical Notes, Suggestions and New Instruments

MULTIPLE CARCINOMAS

A CASE OF FOUR CONSECUTIVE PRIMARY CARCINOMAS WITH APPARENT CURE

C. A HOLLAND, M.D., PHILADELPHIA

Since first reported by Billroth in 1860, multiple primary carcinoma has been found with relative frequency. No longer can multiple primary malignant growths be considered pathologic curiosities and "remarkably rare." [1]

The incidence has been estimated at from 0.3 to 4.33 per cent. Warren and Gates [2] in their statistical survey of recorded cases report an incidence of 3.7 per cent. Hurt and Broders [3] found 3.34 per cent in 2,124 cases of cancer, while Hellendall [4] reports an incidence of 4.33 per cent in 685 autopsies

Fig. 1.—Section of breast removed in 1933 showing microscopic appearance typical of adenocarcinoma.

Primary carcinomas may be multiple in one organ or in various structures of the body. They may be synchronous or metachronous: synchronous when of simultaneous occurrence and metachronous when they develop at different times. Criteria have been suggested to establish the independence of multiple growths. Billroth postulated that each neoplasm must show independent histologic characteristics, that each neoplasm must arise from its parent epithelium and that each neoplasm must produce its own metastatic lesions. These criteria, however, are too limited, since it is well known that many carcinomas are slow to metastasize (e. g. the failure of metastasis in 40 per cent of carcinomas of the cervix uteri) and it is conceivable that multiple cancers in one organ, as in the colon,

3. Hurt, H. H., and Broders, A. C.: J. Lab. & Clin. Med. **18**: 765-777 (May) 1933.
4. Hellendall, H.: Am. J. Surg. **40**: 22-35, 1943.

may have the same microscopic appearance. Therefore the broader standards of Warren and Gates are more logical; namely, that each tumor must present a definite picture of malignancy, that each must be distinct and that the probability of metastasis one from another must be excluded.

These authors report, in a survey of 277 cases of multiple cancer, 111 cases in which three or more primary malignant

Fig. 2.—Appearance in June 1939 showing irregularity of the posterior wall of the esophagus at the level of the aortic arch.

growths were found. Hellendall reports a case in which four primary carcinomas of the anus occurred within a period of ten years, and a carcinoma of the cervix uteri which occurred in the eleventh year was healed locally by x-rays but the patient died one year later from carcinomatous involvement of the thoracic duct. The following is the report of a case in which four primary carcinomas occurred in different organs in the same individual. Two were treated by radical surgery and two by roentgen therapy, apparently with complete cure.

Mrs. S. K., aged 55, was admitted to a Philadelphia hospital in March 1928 and exploratory laparotomy was performed. As the head of the pancreas was firm, thickened and palpable, a diagnosis of carcinoma was returned. No biopsy was done, and as the patient received no special therapy for this condition the error in diagnosis was proved by the subsequent clinical course. The changes felt in the pancreas may have been due to a chronic interstitial pancreatitis.

The patient was readmitted to the hospital in August 1933 for a subradical resection of the right breast. The axillary glands and fat were removed but the pectoral muscles were left intact. Examination of the removed specimen revealed a hard nodule 1.5 cm. in diameter, which cut with increased resistance and proved on microscopic examination to be an adenocarcinoma (fig. 1). No involvement of the axillary lymph nodes could be determined.

In January 1934 she again entered the hospital because of the recurrence of a nodule on the chest wall at the site of the previous mastectomy. This was excised, but microscopic examination failed to show evidence of tumor. Following operation the patient received a series of roentgen treatments to the right side of the chest.

The patient was first admitted to Temple University Hospital in June 1939, to the bronchoscopic and radiologic services, complaining of pain and difficulty in swallowing solid and semisolid foods for a period of five weeks and a loss of 5 to 6 pounds (2.3 to 2.7 Kg.) in weight. Substernal pain appeared immediately after the taking of food, while liquids caused less discomfort. X-ray examination of the esophagus, two weeks before admission, showed an irregularity of the posterior wall of the esophagus at the level of the arch of the aorta involving approximately 3 cm. of the esophagus (fig. 2). The lumen of the esophagus was slightly narrowed at this point, but there was no appreciable delay in the passage of the barium mixture. A diagnosis of carcinoma of the thoracic esophagus was made.

Endoscopy, performed by Dr. Chevalier L. Jackson on June 8, revealed a narrowing of the upper thoracic esophagus with ulceration of the mucous membrane at and just below the point of constriction. Tissue removed at biopsy was typical on microscopic examination of squamous cell carcinoma (fig. 3). The diagnosis returned by Dr. Lawrence Smith of the pathologic department was "squamous cell carcinoma, grade 3."

Irradiation was administered by Dr. Edward Chamberlain between June 10 and July 18, five days a week in daily dosages of 100 roentgens (one fourth in each of four positions: anteroposterior, posteroanterior, left posterior oblique and right posterior oblique) *to a total of 3,000 roentgens. This heavy dosage* was well tolerated, with a minimum of skin reaction and discomfort. Roentgenograms of the chest in October showed extensive changes in both lungs thought to be the result of the intensive irradiation. The patient having no dysphagia, the esophagus was not examined until March 1940, when fluoroscopic and roentgen studies of the esophagus by Dr. Edward Chamberlain

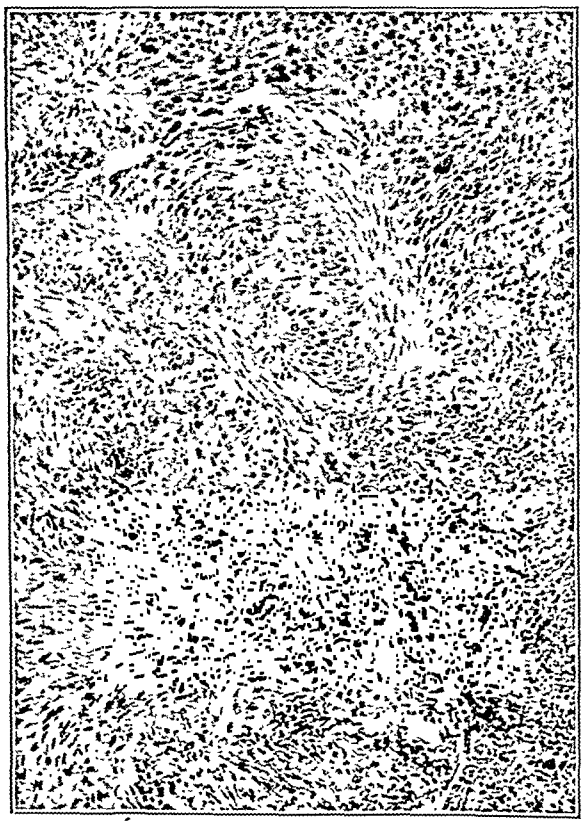

Fig. 3.—Section of biopsy specimen from esophagus showing whorls of pleomorphic cells characteristic of squamous cell carcinoma.

showed no evidence of ulceration or neoplasm (fig. 4). The lumen of the esophagus was ample throughout, and there was no delay in passage of the barium, with no residual barium at the previous site of the neoplasm. Frequent subsequent roentgenograms have shown the esophagus to be apparently normal.

During treatment for the esophageal carcinoma a small basal cell carcinoma of the left cheek was discovered, and one dose of

3,030 roentgens was administered. The growth promptly disappeared and has not recurred.

On July 14, 1942 the patient was again admitted to Temple University Hospital under the care of Dr. W. Wayne Babcock, complaining of intermittent cramplike abdominal pain of two months' duration, with no relationship to time or food. Blood streaked stools were passed on two occasions, but there was no change in bowel habit, the patient having required daily cathartics for years. Barium enema showed an annular carcinoma of the transverse colon near the hepatic flexure (fig. 5) Laboratory findings were within normal limits, with the exception of a moderate anemia.

Fig. 4.—Appearance of esophagus after roentgen therapy, showing no evidence of ulceration or neoplasm.

Fig 5.—Annular carcinoma of proximal transverse colon.

On July 17 resection of part of the transverse and ascending colon was performed by Dr. Babcock with an end to end anastomosis and complemental appendicostomy, and, after a prolonged convalescence resulting from infection and fecal leakage into the obese abdominal wall surrounding the appendix, the patient was discharged August 29 in good condition except for a small draining sinus at the site of the appendicostomy. This necessitated later readmission to the hospital for removal of the infected appendical stump, after which the wound promptly healed.

Examination of the resected portion of the colon showed an annular constricting growth just distal to the hepatic flexure, completely encircling the bowel for a distance of 4 cm, with typical raised, scalloped, firm borders and central ulceration. The neighboring lymph nodes were not enlarged Histologically the growth showed all the features of malignancy, including loss of polarity, pleomorphism, hyperchromatism and infrequent unbalanced mitoses (fig. 6). The diagnosis was adenocarcinoma of the colon, grade 2.

Fig. 6.—Section from ulcerative neoplasm of transverse colon showing loss of polarity, pleomorphism and infrequent unbalanced mitoses

In 1943 the patient, in addition to having developed a mild diabetes which was controlled by diet, had recurrent attacks of upper right quadrant pain accompanied by chill and fever. The last attack was followed by jaundice and resembled the disturbance produced by a stone in the common bile duct. During the resection of the colon the gallbladder was found to be thickened and to contain many stones. A cholecystectomy was performed in November 1943 by Dr. Babcock. Satisfactory exploration of the common bile duct was not accomplished and the cystic duct was anastomosed to the duodenum.

At the present writing, twenty-eight months after removal of the fourth carcinoma, the patient is without physical or roentgen evidence of any malignant disease. She has completely recovered from cholecystectomy and no further symptoms have developed.

SUMMARY

Four metachronous primary cancers occurred in different organs of the body in the same patient within a period of ten years. All apparently have been cured, two by radical surgery and two by roentgen therapy.

This is one of the first recorded cases of carcinoma of the esophagus treated, with five year cure following roentgen irradiation.

POSITIVE PRESSURE RESPIRATION IN THE TREATMENT OF IRRITANT PULMONARY EDEMA DUE TO CHLORINE GAS POISONING

GRACE C. HARDY, M.D., AND ALVAN L. BARACH, M.D., NEW YORK

The development of positive pressure respiration by Barach and Eckman [1] in the United States and by Poulton [2] in England made possible a specialized form of inhalational therapy for bronchial asthma, laryngotracheal obstruction and acute pulmonary edema. The physiologic effects of pressure breathing, the results of its continuous application clinically and various methods of administration have been described previously.[3]

In cases of irritant pulmonary edema in which a continued exudation of serum from the capillaries into the alveoli takes place, despite rest and oxygen therapy, drainage through the respiratory passageway is impeded and bronchopneumonia and death may result. The administration of positive pressure to combat edema of the lungs produced by gas poisoning was suggested by Barach, Martin and Eckman [4] in 1938 in a paper dealing with the therapeutic advantages of positive pressure in the treatment of clinical pulmonary edema. Mention was there made of a case of edema of the lungs described by Norton [5] in 1897 in which a rapid clearance of the edema took place with the use of the Fell-O'Dwyer forced respiration apparatus. Although a theoretical discussion of the mechanism was not given in Norton's report, the recovery of the patient appeared to be due to the introduction of a laryngeal tube and the application of forced respiration under positive pressure.[6]

Carlisle [7] reported that the administration of oxygen with the mask which provided positive pressure in expiration [8] was a most effective method of treating and preventing pulmonary edema due to irritant gases. Rovenstein [9] described a case of irritant gas poisoning in which acute pulmonary edema was successfully treated by the Meter mask, which provided positive pressure in expiration.[10] Segal [11] has also reported the favorable effects of positive pressure respiration in acute pulmonary edema.

The physiologic basis for employing positive pressure in the treatment of irritant gas poisoning is in the main the application of a direct physical pressure on the external surface of the pulmonary capillaries. Approximately 50 per cent of the applied intrapulmonary pressure is lodged on the capillary wall, the remainder being taken up by the elasticity of the expanded lung.[4] Although positive pressure in both cycles of respiration is a more effective method, the application of positive pressure during expiration alone is simpler. In this case the Meter mask with the pressure regulated in expiration by a disk with varying sized outlets was used.[10] When a flow of 8 liters of oxygen per minute is administered with the Meter mask at an oxygen concentration of 50 per cent the incoming air through the injector distends the collecting bag so that a very slight positive pressure is momentarily obtained at the start of inspiration in addition to pressure during expiration.

Other significant physiologic effects of positive pressure respiration are (1) the maintenance of a more patent bronchial passageway, since pressure breathing has been shown to increase the diameter of bronchi in spasm during the expiratory cycle [12] and (2) a variable retarding effect on the entrance of blood into the right side of the heart, this factor being especially manifest in circulatory failure.[4]

The patient who is the subject of this report demonstrates the specific value of positive pressure respiration, since inhalation of 40 per cent oxygen had been continuously used prior to the employment of pressure.

REPORT OF CASE

H. K., a boy aged 11 years, inhaled at a single inspiration some freshly prepared chlorine gas while visiting in a friend's play laboratory. Painful, persistent coughing ensued for two hours, then codeine ½ grain (0.032 Gm.) hypodermically resulted in comparative temporary relief. After one hour the persistent cough returned with labored rapid breathing, exhaustion, vomiting and rapid thin pulse. At this time auscultation revealed loud rhonchi throughout the chest bilaterally. These sounds simulated the creaking of leather, and no moisture appeared to be present. Five hours after the accident he was put in a tent which provided an atmosphere of 40 per cent oxygen and the cough was somewhat relieved. The pulse, however, maintained its poor quality and increased in rate; rapid respirations continued with infrasternal retraction. After four hours in the tent fine moist rales were present in the left lower lobe laterally and at the left border of the heart. Severe headache developed and nausea continued. Fifteen hours later the pulse was feeble, rapid and at times irregular; cyanosis was recognizable; the respiratory rate was 44 per minute. At this time, thirty hours after the accident, the Meter mask was applied with 4 cm. pressure and 50 per cent oxygen. Fine moist rales were now present at both lung bases and over the left lung laterally and posteriorly. Half an hour after positive pressure was applied the cyanosis and headache disappeared and the boy was cheerful and comfortable. Three and a half hours later the moist rales had disappeared from the lung bases but remained in the left lateral area. During the night, while asleep, the patient pulled off the mask and in the morning the general appearance of illness, headache and moist rales at the bases reappeared. After reapplication of the mask with the original pressure adjustment for four hours the rales again diminished and in the next twelve hours the pressure was gradually lowered to zero and the lungs were clear. Oxygen was discontinued. A few rhonchi and wheezing sounds returned for a day but the child was clinically well. The degree of circulatory failure which developed rapidly seems worthy of note. After the lungs were clear, the pulse did not return to normal for three days; weakness and listlessness continued for a week. The patient then recovered completely.

SUMMARY

A patient with irritant pulmonary edema due to inhalation of chlorine gas showed prompt improvement after breathing under a positive pressure of approximately 4 cm. of water during expiration. In spite of previous inhalation of 40 per cent oxygen in a tent, cyanosis, pulmonary edema and obstructive dyspnea had developed and progressed. The favorable clinical response demonstrated that positive pressure respiration was the specific therapeutic agent in the recovery of this patient.

Council on Foods and Nutrition

SPECIAL ARTICLE

This is the sixth of a series of articles discussing the significance of protein nutrition in health and disease. This material was prepared by the authors at the request of the Council and has been authorized for publication.

GEORGE K. ANDERSON, M.D., *Secretary.*

THE IMPORTANCE OF PROTEINS IN RESISTANCE TO INFECTION

PAUL R. CANNON, M.D.
CHICAGO

Interest in the problem of undernutrition has developed increasingly in recent years, largely because of the relationship of food shortages to rising death rates from disease. Moreover, the great amount of undernutrition brought about by the war has reemphasized in particular the nutritional importance of proteins with respect to the normal processes of growth, lactation, fluid balance, bone marrow functioning, recovery from shock, wound healing and immunity. In this brief review especial emphasis will be placed on the influence of protein metabolism on resistance to infection.

In approaching the problem of infection and resistance as a whole it is important to bear in mind that all pathogenic micro-organisms are foreign proteins; therefore, from the standpoint of the host, resistance to them is basically a protein problem, i. e. a problem of protein digestion. When resistance is of a high degree either the invading micro-organisms are destroyed quickly by the phagocytes or their intercellular growth is stopped. When phagocytosis functions speedily and directly, as it usually does in natural resistance, the infectious agents are unable to establish themselves in the tissues of the host; when, on the other hand, phagocytosis is less effective, antibodies may appear, thereby reenforcing the phagocytic mechanism and setting in motion the processes of acquired resistance. In either type of immunity the outcome of an infection depends primarily on the efficiency with which the combined cellular and humoral defense mechanisms cooperate to inhibit microbic growth. Bacterial growth tends to terminate whenever the micro-organisms are engulfed by phagocytes, depending, however, on the digestive capacity of the phagocytes in relation to the particular bacterium engulfed. With virus infections the process is somewhat different in that intracellular parasitism may at times protect the viruses from phagocytes; hence antiviral immune mechanisms may differ in some respects from antibacterial ones. With most types of bacterial infection the outcome depends on the shifting balance between the potentiality of the invading micro-organisms to multiply and disseminate and the efficiency with which the phagocytes ingest and destroy them. If phagocytic action is sluggish, the infection may progress and even become lethal. For example, Lushbaugh [1] has demonstrated that, if rabbits immune to a virulent pneumococcus are intoxicated by alcohol and then infected intradermally with the same strain of pneumococcus, the sluggish inflammatory response caused by the paralyzing action of alcohol on the blood vessels in the area of inoculation may lead to a delayed mobilization of phagocytes and a consequently severe and often fatal bacteremia. Under normal conditions, however, effective phagocytosis tends to favor the speedy localization and destruction of the infective agents. To the extent, therefore, that phagocytosis restricts bacterial growth and thus ensures an adequate resistance, a continual supply of phagocytes is necessary, which requires, in turn, an abundant reserve of phagocytes and their precursors in the mesenchymal tissues (spleen, bone marrow, lymph nodes and lymphoid tissues, liver). These cellular reserves are usually abundant, but when their continuous replacement is hampered by atrophy induced by old age or by prolonged undernutrition or malnutrition the numbers of potential phagocytes from these mesenchymal tissues may become correspondingly diminished. Under such circumstances an infection which might ordinarily be of minor significance may now become menacing, in view of the reduced numbers of phagocytic cells available at the time of need. Furthermore, in the course of progressive undernutrition the total amount of protein nutriment which can be withdrawn from the reserve protein stores will eventually become so depleted that nourishment of the mesenchymal tissues will be seriously impaired, with a resulting tissue atrophy. Under such conditions any opportunistic type of intercurrent infection which would ordinarily be of minor import may now become progressively more severe because of the inability of the mesenchymal reserves to supply phagocytes at a rate commensurate with demands.

Besides these quantitative requirements for a large reserve of phagocytic cells, qualitative adequacy of the phagocytes is also essential. For example, it has been demonstrated by Strumia and Boerner [2] that immature leukocytes, such as myeloblasts and myelocytes, when tested under comparable conditions, manifest less phagocytic ability than do mature polymorphonuclear leukocytes and that phagocytic ability in general varies directly with the degree of functional maturity of the phagocytes. Recent evidence suggests that phagocytic potentialities of polymorphonuclear leukocytes may be impaired by various nutritional deficiencies. Cottingham and Mills [3] report that dietary deficiencies of protein and of certain vitamins, viz. thiamine, pyridoxine, riboflavin, ascorbic acid, choline and pantothenic acid in young white male mice may all depress phagocytic activity in vitro. With respect to protein intake they found a direct relationship between the amount consumed and the degree of phagocytic activity. These investigations should be pursued further in the living animal in order to ascertain more precisely how these dietary deficiencies may modify natural resistance.

Of particular importance in antimicrobic defense, however, is acquired resistance; all pathogenic micro-organisms, because they are foreign proteins, are capable within the tissues of activating the antibody mechanism. Antibodies so engendered may or may not be cast into the circulating fluids in large amounts, depending on the intensity of the antigenic stimulus, the quantity and character of the antigen reaching the antibody producing tissues, and other factors. But, regardless of the antibody content of the circulating plasma the antigen activates the mechanisms of acquired resistance, and

these mechanisms may persist, to be reactivated later by specific or nonspecific antigenic stimulation. This specifically acquired resistance to a wide variety of potentially pathogenic micro-organisms represents a type of biologic adaptation which conditions a child in the early years to many clinical and subclinical infectious experiences. After the micro-organisms have been effectively resisted, the resultant immunity tends to persist, to be reawakened or restimulated in the course of later infections. This ability to respond with an accelerated reactivity to later antigenic stimulations is referred to as the anamnestic response; elsewhere I[4] have discussed the nature of this phenomenon and its relationship to antibody production and resistance.

Evidence that the antibody mechanism may remain quiescent for a long time is seen in the fact that, after infection or vaccination, specific antibodies may tend to persist in low concentration or even to disappear from the blood serum, only to reappear in greater immediate concentration after antigenic stimulation, as following a so-called "booster" injection.[5] It is evident, therefore, that it is not the fact of antibody concentration in the blood serum at any particular moment that is so significant in resistance as that there has been a retention of the capacity of the antibody producing tissues to become reactivated and thereby enabled to resist bacterial agents against which they have once been immunized. The persistence of this antibody producing capacity may be explained by the supposition that a protein matrix exists within the tissues from which antibodies arise, and in the course of their fabrication the antigen unites in some way with this matrix to form a common union, which may then persist, regardless of the amount of antibody originally liberated into the circulating fluids.[6] The supposition is, moreover, that this matrix is composed of globulin from which is derived the antibody globulin of the immune serum. According to current views concerning the nature of antibody synthesis, it is assumed that antibody globulin in the blood serum is actually normal serum globulin which has been specifically altered during intracellular synthesis in the antibody producing cells because of its configurational relationship to antigen. In accordance with this view, therefore, antibody production should be influenced by the same conditions which determine globulin production; moreover, as globulin production is dependent on the intake of amino acids and is impaired by an inadequate intake of dietary proteins, antibody production must similarly depend on protein intake.

The earlier hopes of some nutritionists that specific food constituents might be discovered which could enhance natural resistance have not been realized; indeed, evidence justifying such hopes has been disappointingly meager. Moreover, the probability that some type of vitamin may be found which can elevate resistance has not been strengthened by the facts at hand. At the present time there is little reason to hope, furthermore, that optimal nutrition, whatever that may prove to be, will be likely to activate some kind of bacteriostatic agent, which in turn will act prophylactically to inhibit infection. On the other hand there is abundant evidence that the absence of good nutrition may induce a decreased resistance to bacterial infection, as is seen, for example, in the development of various types of infection accompanying prolonged periods of starvation. The important question remains, however, What resistive mechanisms are most deleteriously affected in the course of undernutrition?

The influence of malnutrition and undernutrition on susceptibility to infection is indicated especially by the long known tendency of undernourished persons to acquire severe tuberculosis, rheumatic disease and respiratory and enteric infections. Moreover, in malnourished persons with debilitating diseases, such as cirrhosis of the liver, nephritis or nephrosis, gastrointestinal cancer or ulcerative colitis, there is often a well defined tendency to develop intercurrent infections. Many of these diseases also exhibit the consequences of starvation, as evidenced by a severe loss of weight.

One important effect of prolonged starvation is hypoproteinemia. In an earlier study of this problem[7] it was stated that, in a series of patients dying from various types of chronic disease, hypoproteinemia was one of the outstanding clinical findings. Among these hypoproteinemic patients, moreover, the high incidence and severity of terminal infections was noteworthy. For example, in those with total serum protein values of approximately 5 Gm. or less per hundred cubic centimeters a serious infection in most instances dominated the terminal days of life. The simultaneous occurrence of hypoproteinemia and increased susceptibility to infection suggests the possibility of a mutual relationship.

Much recent evidence indicates that a pronounced reduction in the concentration of serum proteins signifies a reduction also in the tissue protein reserves. Thus it has been shown that there is a dynamic relationship between the serum and tissue proteins, so that the loss of one or the inadequate formation of the other may lead to a reduced protein concentration in both the blood and the tissues.[8] Inanition, wasting disease or protein loss (proteinuria) may all lead in varying degrees to hypoproteinemia, and when depletion of the protein reserves falls below a certain critical level further processes of protein metabolism, whether evidenced as tissue growth or as serum protein fabrication, are thereby also reduced. Although the first effect of hypoproteinemia is manifested as a hypoalbuminemia, it may later be manifested also as a hypoglobulinemia. As both serum albumin and serum globulin are complex proteins fabricated in the tissues and contributed to the blood, impaired production of one or both will seriously hamper their functional utilization, as exemplified by the development of nutritional edema in relation to hypoalbuminuria and by the loss of resistance to bacterial infection in relation to hypoglobulinemia.

Because of the more general interest in albumin synthesis and function, less attention has been given to the effects of undernourishment on the synthesis of serum globulin, although globulin synthesis is fundamental to the problem of antibody formation.[9] The importance of globulin metabolism has not been fully appreciated because of the inadequate understanding of the significance of serum globulin as it is usually evaluated in the albumin-globulin ratio. Because of the fact, moreover, that at times in cirrhosis of the liver or in nephritis or nephrosis there may be a reversal of the albumin-globulin ratio, some workers have concluded that hypoglobulinemia rarely occurs. This may be true in a general sense, but one important fact has

been overlooked, viz. that from the standpoint of antibody globulin and the antibody globulin reserves only a portion of the serum globulin, that is, the gamma fraction, is significant. This gamma fraction is not even demonstrated by ordinary chemical methods of fractionation. Furthermore, in some conditions, as nephrosis, elevation of the alpha and beta fractions of globulin may give the false impression of an increase in total serum globulin, whereas the antibody containing gamma portion may actually be considerably reduced.[10]

In the process of synthesis of gamma globulin in human tissues the important fact should be kept in mind that the body must fabricate a complex serum protein fraction composed of several of the amino acids essential for man. Thus amino acid analysis has shown that human gamma globulin contains appreciable amounts of lysine, methionine, tryptophan, threonine and leucine.[11] Any protein which contains at least five of the eight amino acids considered essential for maintenance of nitrogen equilibrium or of the two additional amino acids which appear necessary for normal human function can assuredly be synthesized only if these amino acids are available either in the protein reserves or in the dietary protein. Obviously such a synthesis cannot readily occur in the face of prolonged protein deficiency and resulting depletion of the tissue protein reserves. Under such conditions, indeed, one would expect definite impairment of the capacity of the depleted tissues to fabricate antibody gamma globulin and thus to contribute antibodies in the course of a developing or impending infection. This has been shown experimentally to be the case.[12] For example, animals (rabbits and rats) subjected to prolonged protein undernutrition exhibit a pronounced loss of capacity to fabricate antibodies and to resist infection. Their antibody producing ability can be quickly restored, however, by ingestion of adequate amounts of high quality protein.

These facts suggest the need, therefore, of an abundant supply of high quality dietary proteins in all persons who have developed a severe protein deficiency in order to bring about repletion of their depleted tissue protein stores. This replenishment of the protein reserves becomes especially important in surgical patients, particularly in those who have lost much weight. Thus, Studley[13] has shown that the incidence of postoperative complications (wound disruption, infection, death) is considerably higher in patients who, before operation, have lost more than 20 per cent of their normal weight. Such patients are also frequently hypoproteinemic. If, after rehydration, the concentration of total serum protein in these patients is low, for example, under 5 Gm. per hundred cubic centimeters of serum, it may be possible to restore their protein reserves preoperatively by blood and plasma transfusions, intravenous or oral administration of protein hydrolysates and/or by more intensive dietary attention to caloric, vitamin and protein intakes. It is recognized, of course, that at times this does not seem to be possible, as in severe liver disease or in nephrosis, but the further loss of blood and tissue proteins may be at least reduced. Furthermore, even here protein repletion may occur in the globulin forming tissues, although the production of albumin is seriously impaired.

In summary it may be said that in the past few years much evidence has accumulated indicating the basic importance of protein metabolism in relation to the processes of natural and acquired resistance. This evidence points more and more to the conclusion also that many important aspects of the problem of infection and resistance are essentially nutritional.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following report. HOWARD A. CARTER, *Secretary.*

DIATHERMY AND RADIO INTERFERENCE

The Federal Communications Commission has just completed a most extensive survey of the communication services of the radio spectrum. In a news release May 17, 1945 the commission announced its final frequency allocations to the nongovernmental radio services in the portion of the spectrum between 25 and 30,000 megacycles with the exception of the region left unassigned for frequency modulation pending the outcome of certain tests now under way. The frequency allocations for scientific, industrial and medical devices including diathermy apparatus are as follows:

Wavelength (Meters)	Dominant Frequency (Megacycles)	Frequency Band (Megacycles)	Band width in per Cent, Approximately
21.95	13.660*	13.653 13.667	±0.05
10.98	27.320	27.185 27.455	±0.5
7.32	40.980	40.960 41.000	±0.05

* The 13.660 megacycle band was assigned previously.

In its proposed report on Jan. 15, 1945 the commission recommended a 30 kilocycle channel (0.05 per cent) for the 27 megacycle region, but in the final report on the recommendation of the manufacturers of diathermy apparatus the commission assigned a 270 kilocycle band, which corresponds to 0.5 per cent channel width approximately. The other allocations for scientific, industrial and medical devices were left unchanged. The commission requested that all equipment be adjusted and maintained as closely as possible to the dominant or middle frequency in each band.

The high frequency energy generated by diathermy equipment has been known to interfere with radio communications. For this reason the commission was obliged to allocate frequencies for medical and surgical applications and for industrial heating. The high frequency electrical energy generated by short wave and long wave diathermy is much the same electrically as that generated by radio broadcasting apparatus. Although the diathermic energy is supposed to be absorbed by the tissues, unfortunately some of it is not and is radiated into space. This energy, if on the same wavelength as established communications, may cause interference.

It is generally agreed among the manufacturers of diathermy machines that band widths of 0.5 and 0.05 per cent will increase the cost of equipment and the service expense. Apparatus made to operate on the narrower channel (0.05 per cent) will cost much more, according to the estimates of the manufacturers.

The Council has given most careful consideration to the entire problem of radio interference by diathermy equipment. In view of the general interest which has been displayed, the Council desires to discuss the matter.

At its recent annual meeting (Feb. 12, 1945) the Council on Physical Medicine of the American Medical Association voted that in the interest of public relations it desires to support the stand of the Federal Communications Commission and that it does not care to be in opposition to the federal agency which is responsible for this important decision.

Furthermore, the Council voted that the suggestion by some of the manufacturers to confine diathermy to one single frequency was unwise. The Council believed that three frequency channels might well be allocated for diathermy, the width of these channels to be decided by the commission.

The Council's decision was based on consideration of the relative importance of serious communication requirements and those of diathermy and the fact that the cost of meeting the situation on the part of the profession is an insignificant part of the whole cost of medical care.

The following facts entered into the Council's deliberations:

1. That diathermy is a useful therapeutic procedure for applying heat to the tissues of the body.

2. That diathermy is not the only method of applying heat for therapeutic purposes, though it is the most effective method known for administration of deep heat.

3. That medical diathermy has interfered with radio communications.

4. That successful operation of medical diathermy does not necessitate radiating high frequency electrical energy into space. In other words, the radio energy dispersed is a by-product and the diathermy equipment would be much more efficient electrically if this energy did not escape but was absorbed by the tissue.

5. That controlled diathermy apparatus designed to operate on a narrower tolerance will cost more per unit than previous equipment.

6. That the therapeutic efficacy of the frequency controlled diathermy apparatus is the same as that of prewar uncontrolled apparatus.

7. That screening the diathermy equipment is one solution of the problem though not practical in many instances. Screening is expensive if the decorations (papering and plastering) of the treatment room are taken into consideration and, furthermore, the mobility of the equipment is limited.

8. That the problem is one of sound medical services and questions pertaining to public relations.

The Council studied two points of view which were raised by the specialists in this field:

1. That there are a number of physicians specializing in physical medicine who are responsible for the operation of physical therapeutic departments in hospitals and in private offices and that these physicians are mindful of budgets and expense of equipment. These specialists, and likewise the Council, are not pleased with the prospects of paying higher prices for diathermy apparatus which are no better therapeutically than uncontrolled devices.

2. That a larger group of physicians do not employ diathermy to any great extent, if at all, in their practice and are not greatly interested.

For several years the medical profession has been accused by various radio interests of interfering with radio communication and of usurping too much of the radio spectrum. This is not good public relations. Those radio interests are of considerable importance, as, for example, the police, Coast Guard, Army, Navy, television, frequency modulation, and other services. In spite of the fact that some physicians might be called on in the future to pay a higher price per unit for diathermy apparatus, the Council chose the approach which in its opinion will benefit the greater number of the profession, e. g. maintaining cordial public relations, and decided to accede to the recommendations of the Federal Communications Commission.

The Council has filed a request with the Federal Communications Commission to allow at least five years for physicians to liquidate their investment in existing diathermy apparatus before being asked to screen them, dispose of them, change them or purchase apparatus which will be frequency controlled.

Some diathermic equipment, especially in hospitals and office buildings of steel construction, may be screened sufficiently so that it may cause little or no interference with radio communications. In these few instances the commission may not insist on any change. The extent of interference will be determined by measuring devices manned and operated by the Federal Communications Commission. If the commission accedes to the Council's request to provide a period of several years for the physicians to make the change, it is unreasonable to think that a physician practicing physical medicine and using diathermy extensively will find his hospital department broken up or his practice ruined.

Surgical diathermy is not regarded as a source of serious interference to communications, and hence the Federal Communications Commission does not contemplate the regulation of this service.

The Council believes that the commission is serving the best interests of the public at large and of the majority of the medical profession in the United States. These public relations are not confined to this nation alone but to Canada, Mexico and other countries. Hence another agency, namely the International Radio Advisory Committee, a subcommittee of the Department of State, is authorized to make necessary preparations for treaties with other nations of the world. The aforementioned allocations the commission states are subject to change necessitated by international agreements.

Advances in technology often create sociological problems which have to be settled by compromises. This is another manifestation of sacrifices by a smaller group made necessary or advisable in the interest of tranquil and cordial relations for the benefit of the public at large.

The Council on Physical Medicine believes that the Federal Communications Commission has studied the problem very carefully and that the commission is fully informed about the questions pertaining to medical service and public relations. The Council hopes that the decisions reached by the commission will be satisfactory to all concerned.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional article has been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its actions will be sent on application.

AUSTIN SMITH, M.D., *Secretary.*

AMIGEN.—A hydrolysate of casein prepared by digestion with porcine pancreas. Amigen is claimed to include all essential amino acids and some di- and tri- peptides.

Actions and Uses.—Clinically, amigen is effective as a means of creating a positive nitrogen balance and can be used as a source of dietary nitrogen. It is not designed to cure disease but to supply nourishment. It may be administered by mouth or injected intravenously and probably is metabolized as required by the tissues.

Dosage.—Amigen is available in powder form for oral use and in solution for parenteral use. The dosage is determined by the weight and physical condition of the patient, past dietary history and present food nitrogen intake. An adequate protein intake for adults is about 1 Gm. per kilogram of body weight per day. For practical purposes 1 Gm. of amigen may be regarded as approximately equivalent to 1 Gm. of protein. Nine Gm. of amigen is claimed to provide 33 calories.

Parenteral administration of amigen is indicated when the patient cannot or should not obtain sufficient protein by mouth, and when the patient cannot assimilate protein. It is contraindicated in the presence of severe hepatic insufficiency and in acidosis until the latter condition is corrected. Untoward effects include nausea, vomiting, hyperpyrexia, vasodilatation, abdominal pain, twitching and convulsions, edema at the site of injection, phlebitis and thrombosis. Injections should be discontinued immediately if alarming reactions occur.

Solution of amigen should not be used if it is cloudy or if sediment is present. Once the bottle is opened, all the solution must be used during one injection and any part not used must be discarded. The unopened bottle should be stored in a cool place.

MEAD JOHNSON & COMPANY, EVANSVILLE, IND.

Amigen Powder: 454 Gm. containers.

Flavored Amigen: 454 Gm. containers.

Amigen 5% in 5% Dextrose Solution: Bottles of 125 cc., 500 cc. and 1,000 cc. Each 100 cc. contains 5 Gm. of amigen.

Amigen 10% Solution: 125 cc. and 500 cc. bottles. Each 100 cc. contains 10 Gm. of amigen.

SATURDAY, JUNE 2, 1945

THE WAGNER-MURRAY-DINGELL BILL (S. 1050 OF 1945)

On May 24 Senator Wagner introduced into the Senate of the United States the bill about which there have been so many conjectures and preliminary announcements during the last few months. The text contains 185 pages. The measure was referred to the Senate Committee on Finance, of which Senator George of Georgia is chairman. The measure was introduced into the House of Representatives by Representative Dingell of Michigan and is there known as H. R. 3293. In the House it was referred to the House Committee on Ways and Means, of which Representative Doughton of North Carolina is chairman. These are the committees to which the previous version was referred.

Elsewhere in this issue appears the first of a series of analyses of this measure, prepared by the Bureau of Legal Medicine and Legislation of the American Medical Association. The present analysis is confined to the section of the bill that proposes a system of compulsory sickness insurance. In subsequent issues of THE JOURNAL attention will be paid to some of the other phases of social security covered by the proposed act. These include grants and loans for construction of health facilities, grants to states for public health services and for maternal and child health and welfare services, also a comprehensive public assistance program and a national system of public employment offices.

The Wagner-Murray-Dingell measure—1945 version—would take over the proposals of the Hill-Burton bill for hospital and health center construction and make of it a ten year program at ten times the cost. This is long term planning with a vengeance, in view of the experimental character of the proposal, at best. Instead of the advisory board with authority proposed by the Hill-Burton measure, the 1945 Wagner-Murray-Dingell bill would substitute a National Advisory Hospital Construction Council, appointed by the Surgeon General and without authority, except to review applications and make recommendations. The new Wagner-Murray-Dingell bill also proposes to extend the grants for venereal disease and for the tuberculosis program. The section on public health service would change the present authorization of $20,000,000 a year for grants to the states with an authorization to appropriate a sum sufficient to carry out the purposes. The annual amount available to the Surgeon General of the Public Health Service for demonstrations, training of personnel and administrative expenses is increased from $3,000,000 to $5,000,000 a year. A formula is established designed to give more aid to the poor states and relatively less to the richer states.

Another section of the 1945 version relates to federal cooperation with the states in providing health and welfare services for mothers and children. The states are to develop their own plans, which are to be approved by the chief of the Children's Bureau. Here also a formula is established for aiding the poorer states to a greater extent than the larger ones.

Section 6 of the measure is devoted to the public assistance program, authorizing federal matching for money payments to the aged, dependent children, the blind and other needy individuals. The seventh and eighth sections provide for an expanded and strengthened national system of public employment offices. Under this section a National Advisory Employment Policy Council is set up to formulate policies and to advise in the administration of the service.

The section of greatest interest to the medical profession at this time is section 9, which would establish a national sickness insurance system. The proponents of the measure minimize its compulsory aspect in every way they possibly can. Nowhere is the word "compulsory" used. In both the abstract of the measure and in Senator Wagner's presentation all the emphasis is placed on the benefits which presumably every one in the United States would receive from this measure; Senator Wagner reaffirms that complete freedom is offered to every one with regard to such medical services as he may give or receive. Indeed, Senator Wagner went so far as to say that "health insurance is not socialized medicine; it is not state medicine." With this pronouncement most people with any understanding of the situation will differ. They will insist that compulsory sickness insurance with federal control is both socialized medicine and state medicine. Health insurance, or actually sickness insurance, is a method of paying medical costs in advance and of distributing such costs. There are differences between various forms of sickness insurance. Senator Wagner emphasizes freedom of medical practice, which he says is carefully safeguarded because each insured person is entitled to choose his own doctor. But he must choose his own doctor from among the physicians or groups of physicians in the community who agree to go into the insurance system. Certainly the insured person cannot

secure the application of any of the funds that he has paid for the payment of a physician who is outside the system. The statement is made that "the participating doctors are likewise free to choose the method through which they are to be paid from the insurance fund." As a rule, they must choose as a group either a fee-for-service plan with a fee table, a capitation fee or a salary. In the summary of the bill released by Senator Wagner the statement is made that "the Surgeon General of the U. S. Public Health Service—a doctor—would administer the technical and professional aspects of the program." This version of the Wagner-Murray-Dingell bill places tremendous authority in the hands of the Surgeon General, as was placed by previous versions. This time there is to be a National Advisory Medical Policy Council, to be appointed from panels of names submitted by professional and other organizations concerned with medical services, education and hospitals and to include also a representative of the public. This council is wholly advisory and without authority. Incidentally, there is nothing in previous law that says the Surgeon General of the U. S. Public Health Service must be a physician. The President can appoint the Surgeon General by selecting any of the members of the regular corps, which includes physicians, sanitarians, economists, doctors of public health and a wide variety of other personnel in the field of medicine.

Among the first of the editorial comments to appear relative to the program for expanded social security was that of the New York *Times*, published on May 26. The *Times* says that certain questions are to be asked of any proposal like the Wagner-Murray-Dingell bill, namely "Will it provide relief where it is needed without producing it where it is not needed? Will it mitigate the penalties for failure or misfortune without weakening the incentives to production and success? Will it provide aid to individuals without making them politically dependent and without dangerously extending the power of the central government?" To these questions the *Times* replies that under the bill as it stands it is more than doubtful whether these questions can be answered satisfactorily. The *Times* points out that vast new programs would be undertaken under the new bill, and existing programs would be tremendously liberalized. The unemployment benefits place a premium on not working. The old age benefits in some instances would pay a man more for retiring than for continuing at his job. The differential treatment would make the states competitors for especially favorable formulas. The total costs of the bill, involving an 8 per cent tax on the payroll, would be a direct tax on employment and would tend to discourage employment at a time when it is our chief problem. Moreover, the *Times* feels that the sponsors have greatly underestimated the actual cost of their measure.

Physicians should obtain copies of this proposed act and study carefully all of its provisions, so that they may see for themselves the extent to which this act would revolutionize medical care in the United States. Senator Wagner points out that he has consulted this time with the American Federation of Labor, the Congress of Industrial Organizations, the Physicians Forum, the Committee of Physicians for the Improvement of Medical Care and the National Lawyers Guild, among other organizations, in obtaining suggestions for modification of his previous version. He has not consulted with the American Medical Association or, as far as is known, with any of the members of its representative bodies or councils. The so-called Physicians Forum is a group of several hundred physicians, mostly inclined toward communism and practically all living in New York City. The Committee of Physicians for the Improvement of Medical Care, once known as the Committee of 400, now maintains a mailing list of around 1,000 physicians and is actually controlled by an inner group of a few physicians who do not in any way represent a majority of medical opinion. Thus the bill completely disregards the majority opinion of the 125,000 physicians who constitute the American Medical Association and who provide the major portion of medical practice for the people of the United States. The bill also disregards the 60,000 physicians now in the armed forces who have sacrificed as much as any other group in the country in the great war in which our nation is now engaged. This obstinacy is typical of the manner in which Senators Wagner and Murray and Representative Dingell have from the first endeavored to impose their notions regarding the care of the public health and of the sick on the people of the United States.

THE HYALURONIC ACID-HYALURONIDASE SYSTEM

Recent work of American and English investigators has extended our knowledge of the hyaluronic acid-hyaluronidase system in several interesting directions of important physiologic, pathologic and therapeutic implications. Hyaluronic acid, previously shown to occur in the vitreous humor, synovial fluid, skin and umbilical cord of various mammals,[1] was found also in the lung[2] and in tumor tissue of various types.[3] Probably hyaluronic acid, free or bound, is a constituent of other cement substances and mucoid matter of mesodermal structures in the body. Its presence may be related to the metachromatic properties of some of these substances, especially such as occur in increasing amounts with progressive age in the walls of large and small arteries. A study of the role of increased capil-

1. Meyer, K., and Chaffee, E.: The Mucopolysaccharides of Skin, J. Biol. Chem. **138**: 491, 1940.
2. Humphrey, J. H.: Antigenic Properties of Hyaluronic Acid, Biochem. J. **37**: 460, 1943.
3. Pirie, A.: A Hyaluronidase and a Polysaccharide from Tumors, Brit. J. Exper. Path. **23**: 277, 1942. Meyer and Chaffee.[1]

lary permeability to the hyaluronic acid content of capillary structures may yield interesting results.

Recent experiments of Meyer, Hahnel and Feiner [4] have shown that solutions of this macromolecular polysaccharide introduced intravenously into rabbits and guinea pigs accelerates the erythrocytic sedimentation, as do other macromolecular colloidal solutions.[5] Studies by Humphrey [2] on rabbits demonstrated that hyaluronic acid bound to horse serum albumin is not antigenic and therefore differs in this respect from the polysaccharides and mucoproteins from pneumococci and other microorganisms. McClean,[6] on the other hand, found that the capsules sometimes formed by streptococci of groups A and C, which contain a polysaccharide, are destroyed by hyaluronidase from various soures, while it does not attack the specific capsular matter of pneumococci, indicating fundamental chemical differences between the capsules of various micro-organisms.

Hyaluronidase, which is one of the "spreading factors," has been isolated from avian and mammalian testicular and cancerous tissues, from filtrates and extracts of staphylococci, streptococci, virulent pneumococci and members of the gas gangrene group, from snake and spider venoms and from leeches. When injected into arthritic joints this enzyme temporarily lowered the viscosity of the synovial fluid without changing the course of the disease and without altering erythrocytic sedimentation.[7] It causes a depolymerization of hyaluronic acid. Capsule formation in young cultures of streptococci of the A and C strains never develops if hyaluronidase is active in such cultures.[6] Meyer and Chaffee [1] consider capsule formation a protective measure against attack from the host on the infecting organisms, thus permitting them to proliferate and increase their virulence, while the production of hyaluronidase by streptococci facilitates their invasion of tissues and their distribution throughout the body. Meyer and Chaffee suggest that similar conditions and interrelations might exist in the case of the hyaluronic acid-hyaluronidase system of cancer.

McClean and Rowlands,[8] and Fekete and Duran-Reynals [9] have shown that hyaluronidase in the spermatic fluid plays an important role in fertilization by dissolving the liquor folliculi and dispersing the cells around the ovum, thus permitting the spermatozoa to reach the ovum. It may be of physiologic importance not only that depolymerization of hyaluronic acid is produced by hyaluronidase but that it proceeds slowly and progressively in the presence of ascorbic acid and oxygen, but without the development of reducing substances.[10]

Current Comment

RANKIN BILL TO ESTABLISH BUREAU OF MEDICINE AND SURGERY IN VETERANS ADMINISTRATION

Representative Rankin, chairman of the House Committee on World War Veterans' Legislation, introduced in the House on May 25 a bill to establish a Department or Bureau of Medicine and Surgery in the Veterans Administration, H. R. 3310. Representative Rogers, Massachusetts, also a member of the committee, introduced a similar bill in the House on the same day, H. R. 3317. Immediately the Committee on World War Veterans' Legislation, to which the bills were referred, scheduled hearings for May 29. This legislation, besides establishing a Bureau or Department of Medicine and Surgery in the Veterans Administration, proposes that commissioned officers and noncommissioned personnel of the department or bureau may be detailed for service with the medical services of the Army and Navy and that commissioned, appointed or enlisted medical personnel of the Army and Navy may be detailed for service with the Veterans Administration when such detail, in the judgment of the heads of the agencies concerned, or of the president, will promote the public interests without impairing the efficiency of the service or services involved. Nowhere is any consideration given to the rights of the men involved. It is further provided that members of the newly to be created Department or Bureau of Medicine and Surgery will be exempt from selection or draft for service with any other component of the armed forces but that any personnel needs of the bureau or department may be filled by assignment of selected or drafted persons. Under this broad authority it would be possible for physicians to be drafted for assignment to the Veterans Administration. Here is more compulsion! Instead of attempting to attract more and better physicians to the Veterans Administration by improving the quality of the service and by making positions sufficiently attractive to well qualified men, these measures propose—at least during wartime—to force physicians who enlisted voluntarily with the armed forces into assignments with the Veterans Administration. The damage that has been wrought to medicine by the destruction of premedical classes, by the threat of state medicine and by the compulsion which has already forced hundreds of physicians into the Veterans Administration is incalculable. The nation will reap this sad harvest for generations to come.

RATS AND RAT BITES

"Man and rat will always be pitted against each other as implacable enemies," Hans Zinsser[1] said. Rats harbor and transmit the infectious organisms responsible for a number of serious diseases of man including bubonic plague, typhus and rat bite fever. They eat the same food as man, they are destructive to the habitations and storehouses of man, and they do not have any compensating beneficial effects on human life whatever. They are an unmitigated pest and nuisance. Rats bite human beings. Elsewhere in this issue (page 324) appears an account of rat biting which will shock even those who had only vague ideas on the subject. Richter reports that almost 25 per cent of the people in a 2 square mile area of Baltimore were bitten by rats over a four year period! Most of the bites were unimportant clinically, but hospital treatment was sought by nearly 100 persons "when the bites had become infected or the skin had actually been torn or chewed away." No doubt a much larger number were treated by physicians in their offices and were not even reported to the health department. About a tenth of those who received hospital treatment for their rat bites developed rat bite fever. From experimental observations it is deduced that rats bite people because they are hungry and will continue to chew unless frightened away. The situation in Baltimore presumably is not any worse than that in most other cities; rats on farms have always been numerous, infesting grain bins, barns and houses. This menace needs to be brought forcefully to the attention of the appropriate civic authorities again and again. Continuous active steps must be taken to control the pest of rats with every means available.

SURGICAL TREATMENT OF PARKINSONISM

In recent articles addressed to the public much has been said about a new surgical attack on paralysis agitans, or Parkinson's disease; indeed, cure of 70 to 80 per cent of patients operated on has been claimed in some of these statements. Recent years have seen much investigation into the cause and treatment of paralysis agitans. One method of approach has been surgical. At present, operations for the relief of paralysis agitans must still be regarded as experimental. Klemme of St. Louis[1] and Bucy of Chicago[2] have both relieved the tremor of paralysis agitans by removal of part of the cerebral cortex, although not the same part. Bucy has removed part of the motor cortex, and in each instance the abolition of the tremor has been followed by a certain measure of paralysis of the extremities. Klemme reports that removal of a portion which he terms the "premotor cortex" has not been followed by paralysis, at least not in all cases. As yet the details of Klemme's operations in the cases studied have not been published. Putnam of New York[3] has relieved the tremor by dividing the pyramidal tract in the spinal cord. Meyers and Browder of Brooklyn[4] have relieved the tremor in some cases by removal of part of the basal ganglions. As yet it has not been possible to assess the relative value of these different operative procedures. None of them can, however, be regarded as a cure. All of them benefit the patient only by alleviating the tremor characteristic of the disease. The other manifestations of the disease remain unaltered. All the operations are followed, at least in some instances, by a variable degree of weakness or paralysis of the arm and leg and at times by other undesirable sequelae. Certainly the surgical treatment of this condition has not yet reached the stage where it can be routinely recommended. The method is worthy of consideration as an experiment in selected and carefully studied instances.

CRYING BABIES

The crying of the newborn baby is a universal negatively directed reaction—a reflex act to unpleasant stimuli. Aldrich and his associates,[1] who studied the crying of newborn infants in a maternity ward nursery, say that good management reduces this crying to a minimum. Evaluation of the pediatric and nursing routines in answering the needs of the newborn infants is a realistic approach to determining causes and means of reducing the amount of crying. The average baby cries one hundred and thirteen minutes a day in the nursery. This is more than should be necessary for the normal use of the cry as a signal of need. The peaks of crying during a twenty-four hour period were found to correspond exactly to the periods when nursing care was at its lowest. The calmest hour of the nursery day occurred at 10 a. m., when the nursery was fully staffed, all babies had been fed and the smaller needs of the infants were more completely satisfied. The hours of most crying were from 10 p. m. on through 2 a. m., at which time there were only two student nurses in the nursery, with thirty babies to care for. Other peaks of crying are explained by adjusting feeding schedules in the nursery to routines of the obstetric ward—visiting hours and supper hours. Crying does not appear to be contagious from one baby to another. The chances are less than 0.14 per cent that more than half of the babies in the nursery will be crying simultaneously. The study indicates that pediatric and obstetric routines, the distribution of nurses through day and night in the nursery, should be adjusted to the community needs of the infants. Other factors, such as the color and lighting in the nursery, the type and nature of babies' clothes and the positions of the babies, may be investigated as contributing to the babies' comfort.

MEDICINE AND THE WAR

ARMY

FIRST MERCY SHIP AFTER VE DAY REACHES AMERICAN SHORES

The first mercy ship to reach American shores after VE day arrived at Charleston, S. C., Port of Embarkation May 10 with 707 wounded men from the European theater of operations. The ship, newest of the Transportation Corps' fleet of twenty mercy liners in the Atlantic, is the Army Hospital Ship *Ernestine Koranda*, named after Army Nurse Lieut. Ernestine Koranda, who was killed in a plane crash in the southwest Pacific during December 1943. The Army Hospital Ship *Ernestine Koranda* formerly was known as the *Dorothy Luckenbach*, an intercoastal freighter, which was later converted into a 750 bed hospital ship in Brooklyn.

SUBCOMMITTEE ON ACCELERATION

The Subcommittee on Acceleration of the National Research Council's Aviation Committee met recently at Wright Field, Ohio, headquarters of Air Technical Service Command to coordinate army, navy and civilian research on flight acceleration conditions. The subcommittee studied the effectiveness of antigravity devices in fighter aircraft and shock forces precipitated by parachutes. The intensive conference program included a demonstration of helicopter flight, a discussion of the pneumatic fever unit and reports from allied air forces representatives.

1386TH SERVICE COMMAND UNIT HONORED

The Meritorious Service Unit Plaque was recently awarded to the 1386th Service Command Unit, Deshon General Hospital, Butler, Pa., "for superior performance of duty by the Headquarters Detachment in the performance of exceptionally difficult tasks, achievement and maintenance of a high standard of discipline during the period of July 1 through Nov. 30, 1944."

NEW COMMANDING OFFICERS IN ARMY HOSPITALS

Col. Harry A. Bishop, who recently returned from the European theater of operations, has been assigned to the post of commanding officer of Welch Convalescent Hospital, Daytona Beach, Fla. Col. Phillip L. Cook, formerly commanding officer of that hospital, has been assigned to Thomas M. England General Hospital, Atlantic City, N. J.

APPOINTED CONSULTING VASCULAR SURGEON

Dr. Charles Goodman, New York, was recently appointed consulting vascular surgeon to the U. S. Veteran's Facilities in the Second Corps Area, which includes U. S. Veterans Hospital 81, New York.

MISCELLANEOUS

WARTIME GRADUATE MEDICAL MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

Illinois

Gardiner General Hospital, Chicago: Peptic Ulcer, Gallbladder and Liver Diseases, Drs. Andrew C. Ivy and Warren Cole, June 6; Thrombosis, Thrombophlebitis and Anticoagulants in Less Common Peripheral Vascular Diseases, Dr. Armand J. Quick, June 13; Chest Diseases and Diseases of the Larynx, Drs. Paul H. Holinger and William E. Adams, June 20; Low Back Pain, Drs. Edward L. Compere and Paul B. Magnuson, June 27.

Station Hospital, Fort Sheridan: Diseases of the Kidneys, Dr. Francis D. Murphy, June 6; Low Back Pain, Drs. Fremont Chandler and Harry E. Mock, June 13; Heart Disease and Allied Conditions, Drs. Newell C. Gilbert and George K. Fenn, June 20; Bone and Joint Infections, Dr. C. H. Hatcher and Lieut. Col. Ralph Soto-Hall, June 27.

Vaughan General Hospital, Hines: Exfoliative Dermatitis Capt. W. W. Tobin and Capt. N. L. Baker, June 1; Arterial Vascular Disease—Traumatic Lesions, Dr. Geza de Takats, June 7; Presentation of Cases, Major S. B. Grimes, June 8; Repair of Bone in Fractures and Diseases, Drs. Edwin Ryerson and Herman C. Schumm, June 13; Palindromic Rheumatism and Rheumatoid Arthritis, Capt. L. M. Schweiger, June 15; Diseases of the Kidneys—Urogenital Tract, Drs. LeRoy H. Sloan and Norris J. Heckel, June 20; Presentation of Allergy Cases, Capt. W. H. Horwitz, June 22; Blood Dyscrasias—Malaria—Filariasis, Dr. Raphael Isaacs and Col. Alexander Marble, June 27; Presentation of Cases, Capt. C. H. Ewing, June 29.

Mayo General Hospital, Galesburg: Heart Disease and Allied Conditions, Dr. Louis N. Katz, June 6; Bone and Joint Infections, Drs. Arthur Steindler and David Markson, June 13; Arterial Vascular Disease—Traumatic Lesions, Drs. Max Peet and Geza de Takats, June 20; Repair of Bone in Fractures and diseases, Dr. J. Albert Key, June 27.

Regional Hospital, Chanute Field: Malignancies in the Army Age Group—Medical X-Ray and Surgical Diagnosis and Treatment, Drs. Alexander Brunschwig and George J. Rukstinat, June 6; Endocrinology, Dr. Willard O. Thompson, June 13; Virus and Rickettsial Diseases—Medical and Neurologic Diseases and Treatment, Dr. Howard Shaughnessy, June 20; Psychosomatic Medicine, Drs. David Slight and Sidney A. Portis, June 27.

Michigan

Percy Jones General Hospital, Battle Creek: Cardiovascular Dynamics, Dr. Richard H. Lyons, June 4; Backache and Vertebral Lesions, Dr. Ralph Ghormley, June 11; Discussion of Testicular Tumors, Major H. Chapnick and staff, June 18; The Post-Scrub Typhus Syndrome, Capt. Mark Dale and staff, June 18; Cast Presentation, Capt. W. E. Peltzer and staff, June 18; Statistical Report of the Work of the Neurosurgical Section Since April 1, 1943, Lieut. Col. Frank H. Mayfield, June 25; Lesions of the Posterior Interosseous Branch of the Radial Nerve, Lieut. John H. Mayer, June 25; Repair of Cranial Defects with Tantalum (Analysis of Cases Done), Lieut. J. J. Byrne, June 25; Causalgia (Analysis of 75 Cases), Lieut. Jack L. Ulmer, June 25.

Virginia

A. A. F. Regional Hospital, Langley Field: Gastroenterology, Dr. Lay Martin, June 29; Traumatic Surgery of the Abdomen, Capt. John B. McKittrick, June 29.

Wisconsin

Station Hospital, Camp McCoy: High Blood Pressure, Dr. John B. Ludden, June 6; Laboratory Diagnosis and Its Relationship to Medical and Surgical Treatment, Dr. Philip F. Cohen, June 13; Conditions Affecting Glucose Metabolism, Dr. Elwood W. Mason, June 20; Brain and Spinal Cord Injuries, Dr. Theodore C. Erickson, June 27.

Station Hospital, Truax Field: Diseases of the Intestinal Tract—Medical and Surgical Diagnosis and Care, Drs. Karver L. Puestow and Erwin R. Schmidt, June 6; Plexus and Peripheral Nerve Injuries, Dr. Theodore C. Erickson, June 13; Dermatologic Diseases, Dr. G. A. Cooper, June 20; Burns and Plastic Surgery, Dr. Anthony R. Curreri, June 27.

VOLUME 128
NUMBER 5

ORGANIZATION SECTION

THE WAGNER-MURRAY-DINGELL BILL—S. 1050 OF 1945

An Analysis by the Bureau of Legal Medicine and Legislation, American Medical Association, May 26, 1945

IN GENERAL

The Wagner-Murray-Dingell bill differs in many respects from the previous one, some of which differences will be italicized or otherwise referred to in this and succeeding analyses. For one thing, it contains ninety-five more pages. Briefly and in broad outline, here is what the bill contains: It adds a new title to the Social Security Act for grants and loans for hospitals and health center construction. This title corresponds closely with the provisions of the Hill-Burton hospital construction bill, with significant exceptions. It provides for grants and services to develop more effective measures for the prevention, treatment and control of venereal diseases and tuberculosis and to extend and improve public health work. It proposes grants to states for maternal and child health services, for services for crippled children and for child welfare services. It would make available grants to states for public assistance to needy individuals, including medical care for such individuals. Section 9 proposes to amend title II of the Social Security Act to provide a national social insurance system. The amended title would provide for (*a*) prepaid personal health service, (*b*) a national system of unemployment and temporary disability insurance (including cash benefits for disability from sickness which causes unemployment), (*c*) retirement, survivor and extended disability benefits, (*d*) a national social insurance trust fund, (*e*) credit for military service, (*f*) extended coverage to include an estimated additional 15,000,000 persons, (*g*) contributions or taxes by employers, employees and the self employed and (*h*) certain general provisions to apply to the operation of the title.

Division of Contributions

Program	Employer	Employee	Total
1. Retirement, survivors and extended disability insurance	1.0%	1.0%	2.0%
2. Medical care and hospitalization insurance	1.5%	1.5%	3.0%
3. Unemployment insurance	1.0%	1.0%	2.0%
4. Temporary disability insurance	0.5%	0.5%	1.0%
Total contributions	4.0%	4.0%	8.0%

Some of the foregoing parts of the bill will be dealt with in subsequent analyses. The present analysis will be confined to that section of the bill proposing a system of compulsory health insurance to be "made available to 135,000,000 persons," in the words of Senator Wagner. In passing, it is perhaps significant to note that the term "compulsory" appears in no place in the releases made available by Senator Wagner to explain the contents of his bill and to construe its provisions. Rather the emphasis has been placed in such releases on the contention that the legislation will not interfere with the normal relationship between the patient and his physician and on the point of view that the health insurance provisions will not be mandatory on the medical profession.

The national social insurance system will be financed in general from a trust fund established by a 4 per cent employer and a 4 per cent employee contribution on wages and salaries up to the first $3,600 a year paid or received after Dec. 31, 1945. The first bill placed the ceiling at $3,000 a year and the employer-employee contribution at 6 per cent each. The contribution to be made by the self employed will be 5 per cent of the market value of services subject to the same ceiling limitation. The contribution by states and localities and by their employees will be 2.5 per cent of the first $3,600. The contributions that employers and employees will make to finance the system will be distributed as shown in the table.

MEDICAL, HOSPITALIZATION, DENTAL, NURSING AND RELATED BENEFITS IN GENERAL

Part A of the amended title II proposes a system of compulsory prepaid personal health service insurance to covered employees and certain specified dependents. As used in this part, the term "personal health service benefits" is defined to include general medical benefits, special medical benefits, general dental benefits, special dental benefits, home nursing benefits, laboratory benefits and hospitalization benefits. There was no provision in the first bill for dental or home nursing benefits. When the term "general medical benefit" is used, it means services furnished by a legally qualified physician or by a group of such physicians, including all necessary services such as can be furnished by a physician engaged in a general or family practice of medicine, at the office, home, hospital or elsewhere, including preventive, diagnostic and therapeutic treatment and care, and periodic examination. The definition in the earlier bill did not refer to services rendered "by a group of such physicians."

The term "special medical benefit" is defined as necessary services requiring special skill or experience, furnished at the office, home, hospital or elsewhere by a legally qualified physician who is a specialist *or consultant* with respect to the class of service furnished, *or by a group of such physicians, or by a group of physicians including such specialists or consultants.*

The term "general dental benefit" is defined to mean services furnished by a legally qualified dentist or by a group of such dentists, including all necessary dental services such as can be furnished by dentists engaged in the general practice of dentistry, with or without the aid of an assistant or hygienist under his direction, and including preventive, diagnostic and therapeutic treatment, care and advice, and periodic examinations. Similarly, the term "special dental benefit" is defined to mean necessary services requiring special skill or experience, furnished at the office, hospital or elsewhere by legally qualified dentists (with or without the aid of an assistant, hygienist or anesthetist under his direction) who is a specialist or consultant with respect to the class of service "furnished by a group of such dentists, or by a group of dentists, including such specialists or consultants."

"Home nursing benefit" means nursing care of the sick furnished in the home by (1) a registered professional nurse or (2) a practical nurse who is legally qualified by a state or, in the absence of state standards or requirements, who is qualified with respect to standards established by the Surgeon General after consultation with the Advisory Council and with competent professional nursing agencies and who furnishes nursing care under the direction or supervision of the state health agency, the health agency of a political subdivision of a state or an organization supplying and supervising the services of registered professional nurses.

A beneficiary entitled to laboratory benefits will receive such necessary laboratory or related services, supplies or commodities as the Surgeon General may determine, including chemical, bacteriologic, pathologic, diagnostic and therapeutic x-ray and related laboratory services, *refractions and other ophthalmic services furnished by a legally qualified practitioner other than a physician,* physical therapy, special appliances prescribed by a physician, and eyeglasses prescribed by a physician or other legalized practitioner. If any of the services, supplies or commodities covered by this definition are provided a hospitalized patient, or by a physician or dentist incidental to services rendered, payment therefor will be included in payments for hospitalization or for services furnished, respectively.

"Hospital benefit" is defined to mean an amount, as determined by the Surgeon General after consultation with the

Advisory Council created by the bill (S. 1161 required the determination to be made "after approval by Social Security Board"): not less than $3 and not more than $7 ($6 in the first bill) for each day of hospitalization not in excess of thirty days in a period of hospitalization, not less than $1.50 and not more than $4.50 ($4 in the first bill) for each day of hospitalization in excess of thirty in a period of hospitalization, and not less than $1.50 and not more than $3.50 ($3 in the first bill) for each day of care in an institution for the care of the "chronic sick." In lieu of such compensation, the Surgeon General may enter into contracts with participating hospitals for the payment of the reasonable cost of hospital service at rates for each day of hospitalization neither less than the minimum nor more than the maximum applicable rates previously mentioned. In S. 1161 such contracts were conditioned on the approval of the Social Security Board.

A new provision relating to these contracts with participating hospitals provides that payment may be included in a contract for inclusive services of a participating hospital and its staff or attending staff and that such payment will not affect the right of participating hospitals to require payments from patients with respect to the additional cost of more expensive facilities furnished for lack of ward facilities or occupied at the request of the patient, or with respect to services not included within a contract.

A hospital may become a "participating hospital" if it is an institution which provides all necessary and customary hospital services and is found by the Surgeon General to afford professional service, personnel and equipment adequate to promote the health and safety of individuals customarily hospitalized in such institutions. The Surgeon General may accredit a hospital for a limited variety of cases and may accredit an institution for the care of the "chronic sick," taking into account, for the purpose of such limited accrediting, the type and size of the community which the institution serves, the availability of other hospital facilities and such other matters as the Surgeon General may deem relevant.

NATIONAL ADVISORY MEDICAL POLICY COUNCIL

The pending bill contemplates the creation of a National Advisory Medical Policy Council. This Council will consist of the Surgeon General as chairman and sixteen members appointed by him without regard to the Civil Service laws and subject to the approval of the Federal Security Administrator. The appointed members will be selected from panels of names submitted by professional and other agencies and organizations concerned with medical, dental and nursing services and education and with the operation of hospitals and laboratories and from among other persons, agencies or organizations informed on the need for or provision of medical, dental, nursing, hospital, laboratory or related services and benefits. A new provision in the bill requires the membership of the Advisory Council to include (1) medical and professional representatives and (2) public representatives, in such proportions as are likely to provide fair representation to the principal interested groups that furnish and receive personal health services, having regard for the functions of the Advisory Council.

Appointed members will hold office for four years, with terms of office staggered, and will receive compensation at the rate of $25 a day for the time spent on official business with the Council plus actual and necessary traveling expenses. The Council will be required to meet not less frequently than twice a year and whenever at least four of the members request a meeting. The Advisory Council will advise the Surgeon General with reference to questions of general policy and administration in carrying out the provisions of this particular section of the bill, including (1) professional standards of quality to apply to personal health service benefits; (2) designation of specialists and consultants; (3) methods and arrangements to stimulate and encourage the attainment of high standards through the services of general or family practitioners, specialists and consultants, laboratories and other auxiliary services, and through the coordination of the services of physicians and dentists with those of educational and research institutions, hospitals and public health centers, and through other means; (4) standards to apply to participating hospitals, to the relations or coordination among hospitals and to the establishment and maintenance of the list of participating hospitals; (5) adequate and suitable methods and arrangements of paying for personal health service benefits; (6) studies and surveys of personal health services and of the quality and adequacy of such services; (7) policies and procedures for determinations of disability; and (8) grants-in-aid for professional education and research projects. Under the first bill the Advisory Council was also directed to advise the Surgeon General with respect to the establishment of special advisory, technical, local or regional boards, committees or commissions. Under the pending bill the Advisory Council is authorized to establish such groups, whose membership may include members of the Council or other persons or both, to advise on general or special questions, professional and technical subjects, questions concerning administration, problems affecting regions or localities, and related matters.

SELECTION OF PHYSICIANS; ACCEPTANCE OF PATIENTS; PANELS

The Surgeon General will be required to publish and otherwise make known in each local area to individuals entitled to benefits the names of medical and dental practitioners and groups of practitioners who agree to furnish services as benefits and to make such lists of names readily available to individuals entitled to benefits. A new provision in the pending bill provides that such lists must include general or family practitioners and qualified specialists and consultants. With respect to qualified specialists and consultants the lists must indicate the class or classes of specialist or consultant services for which each has been qualified. Any physician, dentist or nurse legally qualified by a state to furnish any services included as personal health service benefits will be legally qualified to furnish such benefits, including any group of physicians, dentists or nurses or combinations thereof whose members are similarly qualified. A limitation contained in the first bill conditioning the participation by a physician on rules and regulations prescribed by the Surgeon General has been eliminated.

Likewise a beneficiary may select any practitioner appearing on a panel to treat him subject to the consent of the practitioner or the group of practitioners, as the case may be. This freedom of choice of practitioner is conditioned, however, on the right of the Surgeon General to prescribe maximum limits to the number of potential beneficiaries for whom a practitioner or group of practitioners may undertake to furnish services, and such limits may be nationally uniform or may be adapted to take account of "relevant factors." A restriction in the old bill that the freedom of choice of physician must be exercised in accordance with such rules and regulations as the Surgeon General may prescribe has been eliminated. A new provision, however, has been added to the effect that every beneficiary and every group of beneficiaries will be permitted to make selection of a practitioner through a representative of his own choosing.

As in the bill introduced in the Seventy-Eighth Congress, the services of specialists, or consultants as added by the pending bill, will ordinarily be available only on the advice of the general practitioner. This is modified in the new bill so that such services may be made available on the advice of a specialist or consultant attending the individual or "when requested by an individual entitled to specialist and consultant services as benefits and approved by a medical administrative officer appointed by the Surgeon General."

The Surgeon General will designate what shall constitute specialist or consultant services. He will likewise determine who are qualified to render such services, in accordance with general standards prescribed by him after consultation with the Advisory Council. In establishing standards and in designating specialists and consultants, the Surgeon General will be required to "utilize standards and certifications developed by competent professional agencies" and must "take into account the personal resources and needs of regions and local areas."

PAYMENTS FOR THE SERVICES OF PRACTITIONERS

Payments to general medical and family practitioners or to general dental practitioners may be made (1) on the basis of fees for services rendered, according to a fee schedule, (2) on a per capita basis, the amount being according to the number of individuals entitled to benefits who are on the practitioner's list,

(3) on a salary basis, full time or part time or (4) on a combination or modification of these bases, as the Surgeon General may approve. The method of payment will apparently be determined in each local area as the majority of the general medical and family practitioners or of the general dental practitioners, respectively, may elect. A new proviso authorizes the Surgeon General to make payments by another method from the one selected in a local area to those general medical and family practitioners or general dental practitioners who do not elect the method designated by the majority. Any of the methods of making payments indicated in the foregoing may be used, as the Surgeon General may approve, in making payment to groups of practitioners that contain designated specialists or consultants as well as general or family practitioners. The Surgeon General may negotiate agreements or cooperative working arrangements to utilize inclusive services of hospitals and their staffs or attending staffs and may enter into contracts for such inclusive services.

Payments to designated specialists and consultants may be made on the basis of salary (whole time or part time), "per session," fee for service, per capita or other basis or combination, as the Surgeon General and the specialists and consultants may agree.

Rates or amounts of payment for particular services or classes of services may be nationally uniform or may be adapted to take account of relevant regional or local conditions and other factors. The bill contains a new provision that payments shall be adequate, "especially in terms of annual income or its equivalent and by reference to annual income customarily received among physicians, dentists and nurses, having regard for age, specialization and type of community." Payment will be commensurate with skill, experience and responsibility involved in furnishing service. In any local area where payment for services of a general or family practitioner is only on a per capita basis, the Surgeon General, the bill proposes, shall make per capita payments on a pro rata basis among the practitioners and groups of practitioners of the local area on the panel with respect to those individuals who after due notice have failed to select a general or family practitioner or who, having made one or more successive selections, have been refused by the practitioner or practitioners selected.

In each local area the provision of general medical or dental benefits will be a collective responsibility of all qualified general medical or family practitioners or of all qualified general dental practitioners, respectively, in the area who have undertaken to furnish such benefits.

HOME NURSING BENEFITS

The bill provides that home nursing benefits shall ordinarily be available only on advice of a legally qualified attending physician but may be made available also when requested by an individual entitled to the benefits and when approved by a medical officer designated by the Surgeon General. The method to be used in paying for home nursing services is not clear.

LIST OF PARTICIPATING HOSPITALS

The Surgeon General is directed to publish a list of institutions which he finds to be participating hospitals in accordance with general standards prescribed by him after consultation with the Advisory Council. Any institution which is not included in the list, or any institution having been removed from the list, may petition the Surgeon General for a hearing. The bill provides that the Surgeon General shall exercise no supervision or control over a participating hospital unless it is owned or leased and operated by the United States. No requirement for participation by a hospital may prescribe its administration, personnel or operation.

LIMITATIONS ON GENERAL MEDICAL, GENERAL DENTAL, HOME NURSING AND LABORATORY BENEFITS

The Surgeon General, after consultation with the Advisory Council and subject to the approval of the Administrator of the Federal Security Agency, may determine that every individual entitled to general medical, general dental or home nursing benefits may be required by the physician, dentist or nurse attending him to pay a fee with respect to the first service or with respect to each service in a period of sickness or course of treatment if he believes that such a limitation is necessary and desirable to prevent or reduce abuses of entitlement to the benefits. The maximum amount of such fee may be fixed by the Surgeon General after consultation with the Advisory Council and with the approval of the Administrator of the Federal Security Agency. He may also limit the application of such fees to home calls, to office visits or to both.

A new provision in the bill would authorize the Surgeon General, after consultation with the Advisory Council and with the approval of the Administrator of the Federal Security Agency, to restrict the content of the general dental, special dental or home nursing benefit. On and after Jan. 1, 1947, however, the restricted content of the general dental or special dental benefit must include at least (1) examination (including x-rays) and diagnosis, (2) prophylaxis, (3) extraction of teeth which are considered by the dentist and an attending physician to be or likely to be injurious to the general health of the individual and (4) treatment of acute diseases of the teeth, their supporting structures and adjacent parts, including fractures of the teeth or jaw. He may also fix an age above which the restrictions on content shall apply.

As to the home nursing benefits, restriction of content may limit the service to part time care on an hourly or visit basis or may limit the types of cases for which such benefits shall be available, or the maximum amount of service per case, or otherwise.

The maximum number of days in any benefit year for which an individual may be entitled to hospitalization will be sixty (thirty in the bill introduced in the Seventy-Eighth Congress). This maximum may be increased to not more than one hundred and twenty days in a calendar year if funds are adequate.

No application for hospitalization benefits will be valid with respect to any day of hospitalization if filed more than ninety days after such day, or with respect to any day of hospitalization more than thirty days following the diagnosis of tuberculosis or psychosis, or with respect to any day in a hospital or other institution for mental or nervous disease or tuberculosis.

Likewise the Surgeon General, after consultation with the Advisory Council and with the approval of the Federal Security Administrator, may limit for any calendar year or part thereof the cost of laboratory benefits. Such limitation may relate to a class of services, supplies or commodities, to maximum payments per beneficiary in a benefit year, to a specified fraction of the cost or to combinations thereof.

PROPOSED METHOD OF ADMINISTRATION

The bill provides that the Surgeon General shall perform the duties imposed on him under the supervision and direction of the Federal Security Administrator and after consultation with the Advisory Council *as to questions of general policy and administration.* He will be authorized to take all necessary steps to arrange for the availability of the benefits provided. He will be authorized, after consultation with the Advisory Council *as to questions of general policy and administration* and with the approval of the Administrator to negotiate and periodically to renegotiate agreements or cooperative working arrangements with appropriate agencies of the United States, or of any state or political subdivision, and with other appropriate public agencies. He may, too, make such agreements or arrangements with private persons or groups of persons to utilize their services and facilities and to pay fair reasonable and equitable compensation therefor. He may negotiate and periodically renegotiate agreements or cooperative working arrangements for the purchase or availability of supplies and commodities necessary for the benefits provided in the bill and to enter into contracts for such services, facilities, supplies and commodities.

Except with respect to state or local areas for which other arrangements have been made, the Surgeon General will be directed to appoint local area committees to aid in the administration of the part of the bill relating to compulsory health

insurance. These committees will include representatives of persons entitled to receive services and benefits, the practitioners, the groups of practitioners, institutions and agencies furnishing services as benefits, and other persons informed on the need for, or provision of, personal health services. Such committees, the bill provides, must be consulted at frequent intervals and must be kept informed by the local area officers of the Public Health Service with respect to arrangements for the availability of benefits and policies to be followed.

The Surgeon General will be directed to give priority and preference to utilizing the facilities of state and local departments or agencies on the basis of mutual agreements with such departments or agencies. He may delegate to any officer or employee of the United States Public Health Service or of any federal, state or local cooperating department or agency such of his powers and duties, except the prescribing of rules and regulations, as he may consider necessary and proper. He may, after consultation with the Social Security Board, after consultation with the Advisory Council *as to questions of general policy and administration,* and with the approval of the Federal Security Administrator, prescribe and publish such rules and regulations and require such records and reports, not consistent with other provisions of the bill, as may be necessary.

The Surgeon General will be required to make a full report to Congress, at the beginning of each regular session, of the administration of the functions devolved on him by the bill, and such reports must include "a record of consultation with the Advisory Council, recommendations of the Advisory Council, and comments thereon."

RELATION TO WORKMEN'S COMPENSATION BENEFITS

No individual will be entitled to any personal health service benefits with respect to any injury, disease or disability on account of which any medical, dental, home nursing, laboratory or hospitalization service is being received, or on application would be received, under a workmen's compensation plan for the United States or of any state.

BENEFITS FOR NONINSURED PERSONS

Benefits may be extended to noninsured persons on behalf of whom equitable payments are made or assured by public agencies of the United States, the several states, or any of them or of their political subdivisions. The bill specifically extends this provision to groups of persons for whom the Congress makes provision under the Social Security Act and other acts of Congress.

ADDITIONAL BENEFITS IN CONTEMPLATION

The Surgeon General and the Social Security Board will be jointly given the duty of studying and making recommendations as to the most effective method of providing dental, nursing and other benefits not already provided for and of reporting their recommendations as to legislation from time to time but not later than two years after the enactment of this bill. The studies and recommendations will relate to expected costs for the additional benefits and a desirable division of the costs between (1) financial resources of the social security system or other public fund and (2) payments to be required of beneficiaries receiving such benefits. Specifically, the Surgeon General and the Social Security Board are mandated to study and make recommendations as to needed services and facilities for the care of the "chronic sick" afflicted with physical ailments and for the care of individuals affected with mental or nervous diseases, recommendations as to legislation to be submitted from time to time but not later than three years after the enactment of this bill.

GRANTS-IN-AID FOR MEDICAL EDUCATION, RESEARCH AND PREVENTION OF DISEASE AND DISABILITY

With the exceptions noted, the provisions in the pending bill authorizing grants for medical education, research and prevention of disease and disability are identical with those that were contained in the original Wagner-Murray-Dingell bill. Under these provisions the Surgeon General will be authorized to administer grants-in-aid to nonprofit institutions and agencies engaging in research or in undergraduate or postgraduate professional education. Such grants will be made with respect to each project (1) for which application has been received from a nonprofit institution or agency, stating the nature or the project and giving the reasons for the need of financial assistance in carrying it out, and (2) for which the Surgeon General finds, with the advice of the Council and *after consultation with other federal departments and agencies concerned with research or professional education* that the project shows a promise of making valuable contributions to the education or training of persons useful to or needed in the furnishing of medical, *dental, nursing* hospital, *laboratory,* disability, rehabilitation and related benefits, or to human knowledge with respect to the cause, prevention, mitigation or method of diagnosis or treatment of disease and disability.

Another new provision would make it mandatory that the Surgeon General and the Advisory Council give preference and priority, during the five year period beginning Jan. 1, 1946, to grants-in-aid with respect to projects to aid servicemen seeking postgraduate education as medical or dental practitioners or training for administration of personal health services, disability benefits, rehabilitation services and related services.

To finance this part of the program a certain percentage of amounts expended for benefits from the social security trust fund will be set aside. The amount to be set aside, the bill provides, will equal 1 per cent of the total amount expended for benefits from the trust fund, exclusive of unemployment insurance benefits, or 2 per cent of the amount expended for personal health service benefits after the latter benefits have been payable for not less than twelve months, whichever is the lesser, in the last preceding fiscal year.

EXISTING PREPAYMENT PLANS

Senator Wagner believes that the enactment of S. 1050 will not necessarily result in the displacement of existing prepayment medical service and hospitalization plans. In the statement that he made to the Senate when the bill was introduced, he said:

> There has been much misunderstanding about the part that voluntary hospitals, group service organizations, existing voluntary insurance or prepayment plans and similar agencies may play in the social insurance system. Let me emphasize that our bill makes a place for them, so that they can continue their good work. All qualified hospitals, all qualified medical groups or organizations, will be able to participate in the program as organizations that will furnish services to the insured persons who choose them, they will receive fair payments for the services they furnish as insurance benefits and they will have enlarged opportunities to be service agencies for particular groups or for their communities. This applies to service organizations created by trade unions, consumer groups, employers, nonprofit community groups, churches, fraternal associations, groups of doctors or individual doctors, medical societies or many other kinds of sponsors or combinations of sponsors The bill not only provides for utilizing existing service organizations but it also encourages the creation of new ones
>
> The Blue Cross hospital insurance plans will be able to continue to act as representatives of the participating hospitals and the community groups that own or manage the hospitals, and they will have large opportunities to be important public organizations that facilitate the administration of vital parts of the insurance system The same will be true for many other community and public organizations
>
> Medical service groups (private clinics, salaried staffs of hospitals, group service plans such as the Kaiser or the Ross-Loos plan) furnishing service under the social insurance system would be as free as they are today to select their own staffs and their own method of paying physicians and others on their staffs, irrespective of the method of payment which prevailed among the individually practicing physicians or dentists of the local area.

The bill itself, however, does not specifically mention existing prepayment medical service and hospitalization plans. It does direct the Surgeon General, after consultation with the Advisory Council as to questions of general policy and administration, and with the approval of the Federal Security Administrator, to make agreements or arrangements with private agencies or institutions, or with private persons or groups of persons, to utilize their services and facilities. To what extent the importance and effectiveness of existing plans could be preserved under such agreements or arrangements is a matter about which many will entertain serious doubts.

Council on Medical Service and Public Relations

MEETING OF MAY 10 AND 11, 1945

The meeting of the Council on Medical Service and Public Relations was called to order by the Chairman, Dr. John H. Fitzgibbon, Portland, Ore., in the Council offices, American Medical Association, Chicago.

Council members present were Dr. Edward J. McCormick, Toledo, Ohio, Vice Chairman; Dr. H. L. Kretschmer, Chicago; Dr. Louis H. Bauer, Hempstead, N. Y.; Dr. A. W. Adson, Rochester, Minn.; Dr. James R. McVay, Kansas City, Mo.; Dr. James E. Paullin, Atlanta, Ga.; Dr. Thomas A. McGoldrick, Brooklyn; Dr. Olin West, Chicago; Mr. Thomas A. Hendricks, Chicago, Secretary, and Dr. Joseph S. Lawrence, Director of the Washington Office of the Council.

Other A. M. A. and state society officials present were Dr. R. L. Sensenich, South Bend, Ind., Trustee, A. M. A.; Dr. Charles Fidler, Milwaukee, president, State Medical Society of Wisconsin; Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL; Dr. Edwin P. Jordan, Chicago, Associate Editor of THE JOURNAL; Dr. Carl M. Peterson, Chicago, Secretary, Council on Industrial Health; Mr. J. W. Holloway Jr., Chicago, Director of the Bureau of Legal Medicine and Legislation; Dr. Thomas G. Hull, Chicago, Director, Scientific Exhibits; Dr. Austin Smith, Chicago, Secretary of the Council on Pharmacy and Chemistry; Dr. Victor Johnson, Chicago, Secretary of the Council on Medical Education and Hospitals; Mr. John L. Bach, Director, Press Relations; Mr. T. V. McDavitt, Chicago, Bureau of Legal Medicine and Legislation; Col. Robert D. Bickel, Liaison Officer to the American Medical Association from the Office of the Surgeon General.

Approval of the Minutes of the Meeting of Feb. 13 and 14, 1945.—On the motion of Dr. McVay, seconded by Dr. Bauer, the minutes were approved.

Suggestion for the Formation of Indemnity Insurance Corporation.—Dr. Bauer introduced Mr. Rowland George, president of the United Medical Service of New York, who presented to the members of the Council a plan for the formation of a stock corporation providing prepayment medical expense indemnity on a nonprofit basis. This corporation, according to the plan, was to be formed and operated under the insurance laws of the state of New York. In regard to Mr. George's suggestion, Dr. McCormick moved that the chairman appoint the General Manager and two members of the Board of Trustees and two members from the Council to convey to Mr. George the reactions to his proposal.

The motion was seconded by Dr. Adson and carried.

The following committee was appointed: Chairman, Dr. Edward J. McCormick; members, Drs. West, Bauer, Sensenich and Adson.

The following letter was prepared and sent to Mr. George:

Dear Mr George,

The Council on Medical Service and Public Relations of the American Medical Association appreciates your coming to Chicago to discuss the proposed plan of establishing a national indemnity corporation and placing the matter before it.

The Council is desirous of doing all in its power to carry out the mandates of the House of Delegates of the A. M. A. to stimulate the development of medical society plans and extend the area of coverage so that the whole United States may be covered by such plans.

The Council has considered the statements made by you yesterday, the memorandum on the formation of a national surgical corporation to cooperate with the Blue Cross and medical plans which you left with the Council and also a letter from Mr. William C. Breed Jr. addressed to Dr. Bauer.

It would appear to the Council that your plan is not yet wholly definite as to the following points.

1. You do not yet have a license to operate either in New York or in any other state.
2. You are not yet certain that you will be allowed to use the funds of the Associated Hospital Service and the United Medical Service.
3. It is not yet definite as to the makeup of the board of directors, although at present the idea is to have them all from New York.
4. The holding corporation, while it is to be composed of at least 51 per cent from the medical profession, at present is to be drawn entirely from the United Medical Service of New York or those they may select. It was stated, however, that this might be changed, but how changed has not yet been determined.
5. It was stated that there would be no competition with existing medical society plans and that, as soon as such plans were available, or if they were already available, the national organization would then withdraw from that local field. However, there is no definite statement in either written memorandum that such would be the case.

For these reasons we believe you will understand that the Council cannot approve what is not yet in effect and the details of which have not yet been wholly worked out.

The House of Delegates of the A. M. A. has set up certain minimum standards on both indemnity and service plans and it is the opinion of the Council that any company operating in the field of medical care insurance would have to set up the following minimum specifications in order to meet with the approval and cooperation of the medical profession.

1. Any plan developed must deliver medical control of all medical policies and medical service into the hands of the medical profession.
2. The final approval of the selection of any medical control board set up under 1 should in the last analysis be by a responsible group of the organized medical profession.
3. The plan must not interfere with [illegible] her cash indemnity or service plans developed b[illegible]
4. The practice of hospitals selling [illegible]pproved, and the special services of anesthesiology, pathology, radiology, physical therapy in any other medical service should be covered in the medical contract and not in the hospital contract.

The House of Delegates of the A. M. A. has approved both cash indemnity and service plans with the proviso that these plans are so constituted that (1) they give good medical care, (2) they are approved by the local medical societies involved (although not necessarily actually developed by the medical society), (3) the part played by the A. M. A. is restricted to the adoption of broad general principles and to acting as a clearing house and, (4) since conditions vary in different localities, plans should be largely local in character so far as details are concerned, and national only so far as broad general principles are concerned.

In the development of any cash indemnity national plan, therefore, it would appear that the four items listed in the second preceding paragraph are those that are most pertinent.

Again, permit us to thank you for your courtesy and cooperation.

Sincerely yours,

JOHN H. FITZGIBBON, M.D.
Chairman, Council on Medical Service and Public Relations

Dr. McCormick moved the adoption of the report.

Request for Consulting Committee by Insurance Companies.—Dr. Harry E. Ungerleider and Mr. Wendell Milliman of the Equitable Life Insurance Company, representing a group of large insurance companies, requested that a consulting committee be appointed by the Council to rate various surgical procedures on a unit system for the purpose of insurance reimbursement. Dr. Bauer moved that the Council appoint a consulting committee, including the various surgical specialties, to consider the feasibility of the assessment of the various surgical procedures on a unit system for purposes of insurance reimbursement. The motion was carried.

Dr. Jordan said that the American Medical Association had published a Standard Nomenclature of Operations which would be useful to the committee. Dr. Hull suggested that each member of the committee be supplied with a copy of the book on nomenclature.

Suggestions for Medical Care.—Dr. Lawrence presented suggestions in regard to the medical care problem which were considered by the Council but not approved.

Legislation.—Dr. Lawrence, Mr. Holloway and Dr. Victor Johnson discussed pending national legislation.

Supply of Medical Students.—Dr. Johnson will make a statement in regard to the situation for a Council News Letter.

Commercial Health Insurance Meeting.—It was decided that there should be a joint meeting of the members of the Council on Medical Service and Public Relations and the Council on Industrial Health, or possibly the executive committee of both Councils, depending on the agenda planned by Dr. Peterson and Mr. Hendricks. If insurance men are invited, the full Councils should meet.

Employment of Insurance Study Director.—Dr. McCormick moved that the Council should recommend to the Board of Trustees the selection of the best available talent to institute an insurance study bureau in the American Medical Association headquarters under the direction of this Council, and that the study be under way prior to the meeting of the House of Delegates.

Dr. McGoldrick suggested the following modification: "The Council requests and urges the Board of Trustees to lend every assistance to Dr. West and this Council for the speedy selection of a qualified director of insurance."

The motion as amended was carried.

Insurance Company Programs.—The Liberty Mutual Company program was presented by Dr. Peterson.

Comment on prospectus of G. H. Poulsen & Co., through the underwriting facilities of the Metropolitan Casualty Insurance Company of New York, was made by Dr. McCormick.

An indemnity plan underwritten by a nationally recognized insurance carrier is being prepared by Don Hawkins, insurance executive.

In each case enough copies of these proposed plans were to be obtained for each member of the Council.

Listing and Fellowships for Men in Service.—It was moved by Dr. McCormick and seconded by Dr. Adson and carried "that the Council recommend to the Board of Trustees and officers of the American Medical Association that all members in the military service who have been Fellows of the American Medical Association be carried in the directory as Fellows whether they take THE JOURNAL or not until the cessation, and men entering service if they are Fellows be listed as Fellows in the directory until the end of the war, or until six months thereafter, or the termination of their service."

The motion was amended by Dr. McCormick to read that "they retain their membership."

Committee on Chronic Diseases.—Dr. McCormick moved that "this Council recommend the appointment of a committee on chronic diseases." The motion was carried after amendment to read that "the Council recommend that the Board of Trustees appoint such a committee."

Preparation of Annual Report.—Dr. McCormick moved that the annual report of the Council be sent to state associations for publication in their journals and to THE A. M. A. JOURNAL if a meeting of the House of Delegates is not held. The motion was carried.

Interim Body with Power to Act.—Dr. Adson moved that a committee be appointed which will consist of the executive Committees of the Board of Trustees and the Council which is to implement the activities of the House of Delegates during the interim between their meetings on subjects of public policy. The motion was carried.

American Cancer Society Clinics.—Mr. Louis Neff, director, American Cancer Society, discussed the program of the establishment of clinics by the society.

Dr. McCormick made the following motion after discussion: "The work of the American Cancer Society be supported by this Council with the understanding that all work done in the various counties be done under the supervision of the county medical society and that a committee be appointed by the chairman of this Council to act as an advisory committee of the Council cooperating with the American Cancer Society until such time as the committee on chronic diseases is appointed, when it might seem feasible for this committee to take over the work." The motion was seconded by Dr. McGoldrick.

The committee appointed by the chairman has the following membership: Chairman, Dr. McGoldrick; members, Drs. Bauer and McCormick.

Suggestion for State Society Information Service.—Suggestion that an information service to coordinate the work of the state medical society and the state health department in anticipation of the Hill-Burton bill set up under the direction of the American Medical Association in each state medical society was presented to the Council by Miss Virginia Shuler of the Bureau of Information.

Dr. Paullin suggested "I think it would be fine if this Council endorse the plans as set forth here by Miss Shuler and that such plans be transmitted to the Committee on Postwar Medical Service." It was decided to follow this suggestion.

Material for Journal A. M. A.—Mr. Hendricks stressed the desire of the Council to obtain information from Council members as to public appearances, speeches given and so on for use in the News Letter and also publication in THE JOURNAL.

News Letter.—It was agreed that the names of those doctors who desire the News Letter be added to the mailing list. Also that once or twice a year a questionnaire be included in the issues to find whether or not doctors want to continue receiving the News Letter.

The Council approved having reprints made of the following, and distributed through the News Letter:

1. "Do Not Socialize Your Medical Care," by Dr. John H. Fitzgibbon, from April 1945 issue of The Republican.
2. "Should we have Government Health Insurance?" a debate between Hon. Andrew J. Biemiller and Dr. Louis H. Bauer.
3. Copy of "Status of the English Doctor," copied from the Jackson County Medical Society Bulletin and brought to the attention of the Council by Dr. Lawrence.

Conference of Seventeen Presidents.—Dr. McCormick reported on the conference of seventeen presidents held at Detroit, April 27-28, under the auspices of the Michigan State Medical Society. He reported that this conference passed the following resolution:

Be It Resolved,

1. That this group expresses its continued loyalty to the American Medical Association;
2. That it is the duty of the various state medical societies to advise the American Medical Association, through its Council on Medical Service and Public Relations, of their wishes in regard to national health legislation;
3. That the presidents of the several states and District of Columbia medical societies, or their representatives, act as a permanent committee immediately to set up Drafting Panels in each state for this purpose;
4. That states not represented here today be invited and encouraged to join in this work;
5. That the president of the Michigan State Medical Society be designated as temporary chairman of this committee to facilitate its activities.

Suggestions for Council Work.—Copies of the letters from Charles Crownhart, executive secretary of the State Medical Society of Wisconsin, and John Farrell, executive secretary of the Rhode Island Medical Society, in regard to suggestions, sent to members of the Council.

Letter of Appreciation to Dr. W. S. Leathers.—The Secretary of the Council was instructed to write Dr. Leathers expressing regret because of his resignation.

Regional Meeting in West.—There should be an announcement from the Council that it is planning a meeting in the West and will hold it as soon as possible, when travel conditions improve.

Executive Meeting of the Council.—An executive committee meeting will be held before a full Council meeting is held.

Public Relations Organization Plan.—The suggestion that an organization chart be prepared for the next meeting of the Council indicating its relationship and functions was given approval by the Council. The Council recommended that the Secretary study the public relations plans of large organizations.

Very respectfully submitted,

JOHN H. FITZGIBBON, M.D., Chairman.
THOMAS A. HENDRICKS, Secretary.

Official Notes

DOCTORS LOOK AHEAD

Broadcast on the network of the National Broadcasting Company will include the following programs in the next four weeks:

June 9. They Shall Hear Again: A program devoted to the needs of the hard of hearing and indicating new opportunities for them through the use of hearing aids, lip reading, medical treatment and occasionally surgery. Guest speaker Howard A. Carter, B.S. in M.E., Secretary of the American Medical Association Council on Physical Medicine.

June 16. Home Was Never Like This: A program devoted to the possibilities of the American health resort or spa in the treatment of disease. Guest speaker Dr. Walter S. McClellan, Chairman of the American Medical Association Committee on Health Resorts, speaking from New York.

June 23. Postwar Doctor: Problems in medical education and their influence on the public health. Guest speaker Dr. Victor Johnson, Secretary of the American Medical Association Council on Medical Education and Hospitals.

June 30. Health in Schools: A program devoted to health education and related topics in our schools, in which doctors look ahead to greater progress in the next decade. Speaker Dr. Charles C. Wilson, Teachers College, Columbia University, speaking from New York.

Doctors Look Ahead is heard on one hundred and twenty-three stations of the National Broadcasting Company network each Saturday at 4:30 p. m. Eastern War Time (3:30 p. m. Central War Time, 2:30 p. m. Mountain War Time and 1:30 p. m. Pacific War Time).

Owing to conflicts in schedule, Doctors Look Ahead, which was not heard in Chicago on May 26, will continue to be heard

in Chicago at 3 p. m. Central War Time, but each program as scheduled on the preceding page will be heard in Chicago one week later. Doctors Look Ahead will close with the program of June 30; this will be heard in Chicago on July 7.

BUREAU OF PUBLIC RELATIONS CHANGES STAFF

Mr. Lawrence C. Salter, associate in public relations in the Bureau of Public Relations of the American Medical Association, has resigned, effective June 1. Mr. Salter is establishing a private agency in the field of public relations, particularly as related to medicine and science. Mr. Salter is succeeded by Mr. John L. Bach, who from June 1 will be responsible largely for the preparation of the *American Medical Association News* and for the publicity releases made by the headquarters office of the American Medical Association.

Washington Letter

(From a Special Correspondent)

May 28, 1945.

Surgeon General for Veterans Administration Proposed

Creation of the office of Surgeon General for the Veterans Administration, establishing a setup comparable to the medical corps of the Army and Navy, is proposed in a bill introduced by Representative Rankin, Democrat of Mississippi, after he and Veterans Administrator Frank T. Hines had conferred with President Truman. Rankin said the President had approved the bill "in principle." To give the administrator free reign in selecting personnel, the measure would take veterans' hospital medical personnel out of Civil Service. It would also call for a wartime draft of nurse and other medical personnel for the agency to help get "the best available" medical care for veterans.

Latest development in the probe of charges against the agency of inefficiency in the operation of veterans' hospitals is a move in Congress to have the inquiry taken away from Representative Rankin and his Veterans Committee. It is proposed that Representative Philbin, who has criticized Rankin's conduct of the hearing, head a new investigation. Meantime the Veterans Administration has endeavored to counteract charges against what Brigadier General Hines calls an effort to "destroy confidence" in the agency by launching a publicity campaign through its field offices.

Hearings on Physically Handicapped Continue

Wendell Burge, assistant United States attorney general, supplemented his charges of monopoly in the production, distribution and sale of certain drugs and appliances when he continued testimony before the subcommittee on aid to the physically handicapped. Hearings continued later in the week on the causes, prevention and treatment of epilepsy and general problems of the epileptic. Among witnesses were Dr. William G. Lennox, Harvard Medical School, Boston; Dr. A. L. Van Horn, director of health service, Children's Bureau, U. S. Department of Labor; Frank D. Ashburn, headmaster, Brooks School, North Andover, Mass.; Wilfred B. Johnston, safety engineering instructor, Northeastern University, Boston; Ralph J. Crosby, insurance executive, Marsh and McLennan, New York City; Dr. Jerry Price, Tiffin State Institute, Tiffin, Ohio, and Mrs. Brooks Potter, president, American Epilepsy League, Inc., Boston.

Veterinarians Accused of Fostering Rabies Scares

Dr. Millicent Morden, Brooklyn physician, told a House District subcommittee considering compulsory antirabies vaccinations that many veterinarians deliberately agitate rabies scares to sell serums and charge vaccination fees. Other opposing witnesses said that vaccination spreads rabies instead of preventing it, and James P. Briggs, president of the Humane Educational Society, said no vaccine yet developed justified compulsory use on dogs. Despite these adverse witnesses, District and Federal health department officials backed up the District commissioners in their demands for authority to order vaccinations of dogs during rabies scares. A supporting witness, Dr. William D. Claudy, member of the National Capital Kennel Club, said he had served on a committee to investigate the rabies situation here and quoted American Medical Association reports to back his conclusion that vaccination is "not 100 per cent perfect" but does increase resistance of dogs to rabies infections. Favoring the measure were Dr. Ruhland; Dr. H. C. Schoening, chief of the pathologic division, Bureau of Animal Husbandry; Dr. James G. Cummings, director of communicable disease bureau, District Health Department; Dr. Reed R. Ashworth, and Dr. Claudy. Opposing the measure were Mrs. H. D. Albin, secretary, Animal Protective Association, and others.

Another Hearing on Capital Hospital Center Planned

Another hearing is to be held on the proposed 1,500 bed hospital center for the District, says Representative Murphy, Democrat of Pennsylvania, chairman of the Fiscal Affairs Subcommittee of the House District Committee. At the hearing last week conflicting testimony was given on Washington's need for the proposed center. Henry J. Sullivan, division engineer of the Federal Works Agency, told the subcommittee he believed the Capital should meet its need for hospital facilities by replacing existing obsolete institutions rather than through creation of the new medical center. He submitted survey figures to show that the District now has four hospital beds per thousand of population, and he declared that when new hospitals for Georgetown and George Washington universities are completed there will be 5 beds per thousand persons. He said that authorities agreed the latter figure should be the standard. Wherever the center might be erected, he warned that "in ten or fifteen years you might wish you hadn't." Health Officer George Ruhland, however, supported the center, declaring that recent population growth of the metropolitan area more than justified the 1,500 bed center. His figures submitted at the hearings on the Tydings-Bilbo measure estimated the population of the District at 950,000, with about 1,268,000 concentrated within the metropolitan area. He estimated hospital beds here at 3.7 per thousand of population and declared that the District requires an additional 1,468 beds to assure medical treatment for all needing it. Charles D. Drayton, president of Children's Hospital and chairman of the Hospital President's Association, urged House approval. Representative Bates, Republican of Massachusetts, said he had an "open mind" on the question, but he pointed out that the bill involves a new policy for Congress in providing funds for an enterprise which after establishment would be conducted by private interests.

Capital Notes

Two temporary buildings at St. Elizabeths Hospital, described as "firetraps" and a grave menace to 300 aged or insane inmates, will be replaced by a modern 500 bed structure under a bill approved by the House, which provides over $2,500,000 building funds for the hospital in a Labor Department and Federal Security Agency appropriation.

Present easing of War Production Board controls will not greatly improve meeting drug and pharmaceutical industry requirements for materials and supplies currently on short supply, says John T. Batson, chief of the Drugs and Cosmetics Branch of the Chemicals Bureau, WPB.

Medical supplies for army installations in Florida, Georgia, South Carolina, North Carolina and Virginia, formerly handled at Savannah Medical Depot, will be taken over by the Atlanta Army Service Forces depot, the War Department states.

The Red Cross reports that a million dollars' worth of food and medical supplies for American prisoners of war held by the Japanese have been shipped from a West Coast port to the Russian far eastern port of Vladivostok.

District of Columbia coffers will be swelled by an estimated $500,000 through a drive to collect hospital fees from financially solvent "indigent" patients in St. Elizabeths and other local institutions.

A Negro woman who carried typhoid germs which caused death of another Negro has been warned to stay away from food handling on the threat that if she is caught at such work a third time she will be arrested.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

State Medical Election and Meeting.—Dr. *Philip K. Gilman*, San Francisco, was inducted into the presidency of the *California* Medical Association during its seventy-fourth annual session in *Los Angeles* May 6. Dr. *Samuel J. McClendon*, San *Diego*, was named president-elect. Delegates to the American Medical Association include Dr. *Robertson Ward*, San Francisco, Dr. McClendon, Dr. *Lowell S. Goin*, Los Angeles and Dr. *Dwight H. Murray*, *Napa*. The house of delegates adopted two amendments to the constitution, the first of which made a slight change in the personnel of the state council by abolishing the office of past president, and the second of which removed certain technical difficulties affecting the obtaining of retired membership. A resolution was adopted providing for the establishment of an advisory planning committee to be composed of lay employees of various medical bodies including the executive secretaries of the Los Angeles County Medical Association, the Alameda County Medical Association, the Public Health League of California and the California Medical Association, the associate counsel of the state medical association, the lay representative of the council and such other lay employees as the council of the state association may designate. As constituted at present, the members of the committee will consist of Stanley K. Cochems, Rollen Waterson, John Hunton, Howard Hassard, W. Glenn Ebersole and Ben H. Read. The committee was instructed to study the economic and health factors involved in medical and hospital care problems as at present under consideration or as may hereafter be brought to the committee, to act in other matters as the council of the California Medical Association may from time to time direct and to make reports to the council of the California Medical Association in respect to all of these matters, outlining actions to be taken with reasons therefor. The meeting was held under the presidency of Dr. Goin. The scientific session, which was prepared under the auspices of the Los Angeles County Medical Association, included panel discussions on diseases of the liver and on vascular diseases and symposiums on wartime medicine and psychogenic factors in obstetrics and gynecology. Among the speakers were:

Dr. Harry L. Arnold Jr., Honolulu, The Diagnosis of Early Leprosy.
Lieut. Col. Ralph Soto-Hall, M. C., and Lieut. Col. Morris Thomas [illegible] M. C. An Evaluation of Methods of Treatment of Comminuted Shaft of the Femur.
Ca [illegible] (MC), Modernization of Quarantine Regulations to Prevent the Transmission of Tropical Diseases to the United States.

The symposium on wartime medicine included the following speakers:

Comdr. Richard B. Schutz (MC), Filariasis.
Capt. Louis E. Mueller (MC), Aviation Medicine.
Lieut. Comdr. Milton B. Filberbaum (MC), Cardiac Murmurs and Pain.
Comdr. Walter Rapaport (MC), War Neuroses.

CONNECTICUT

Dr. Peter Goes to Washington.—Dr. William W. Peter, New Haven, has resigned as associate professor of public health and chief of sanitary inspection in the department of health, Yale University School of Medicine, to become director of the training division of the Institute of Inter-American Affairs, Washington, D. C., according to the New York *Times*.

ILLINOIS

Graduate Conferences.—The Illinois State Medical Society will sponsor a postgraduate conference at the Emmerson Hotel, Mount Vernon, June 7, with Dr. Andy Hall, Mount Vernon, presiding, who will speak on "Reminiscences of Fifty-Four Years in the Practice of Medicine." Among speakers will be:

Lieut. Col. Earl R. Denny, M. C., Penicillin.
Dr. Willard C. Scrivner, East St. Louis, Sterility.
Dr. Edward W. Cannady, East St. Louis, Recent Advances in Treatment of Essential Hypertension.
Dr. Frank E. Maple, Chicago, Treatment of Abortion.
Dr. G. Henry Mundt, Chicago, Management of Sinus Disease.
Dr. Edward L. Compere, Chicago, Treatment of Compound Fractures.
Dr. William O. Thompson, Chicago, Recent Advances in Endocrinology.
Dr. H. William Elghammer, Chicago, Rheumatic Fever in Children.
Dr. Edwin S. Hamilton, Kankakee, Future of Medicine.

A similar conference with the staff of the Mayo General Hospital, Galesburg, cooperating was held for western Illinois in Galesburg, May 17. The speakers included:

Capt. Leo A. Kaplan, M. C., Psychiatric Factors Delaying Recovery.
Capt. David I. Abrahamson, M. C., Thrombophlebitis.
Major Harris B. Shumacker Jr., M. C., Traumatic Aneurysms.
Lieut. Col. Philip Lewin, M. C., Fractures of the Upper Shaft of Femur.

Capt. Charles M. Schroeder, M. C., and Capt. Norman T. Welford, M. C., Mayo General Hospital, conducted discussions on the "Use of Penicillin" and Major Richard E. Kinzer, M. C., and Capt. Irving Joshua Speigel, M. C., a symposium on "Ruptured Intervertebral Disks."

Chicago

Committeè on Tuberculous Veterans.—A committee on tuberculous veterans of the Tuberculosis Institute of Chicago and Cook County will hold its first annual meeting June 29 at the central Y. M. C. A. auditorium, 19 South La Salle Street. Dr. William F. Petersen will discuss "Practical Problems in Tuberculosis."

Personal.—Dr. *Norman C. Parfit* on his return to Oxford, England, after spending some years as associate professor of public health in the West China Union University School of Medicine, Chengtu, China, visited the headquarters of the American Medical Association, May 17. Dr. Parfit's wife, Edith Jesse, is also a physician.

Ear, Nose and Throat Refresher Course.—The University of Illinois College of Medicine will hold its sixth semiannual refresher course in laryngology, rhinology and otology, September 24-29. Additional information may be obtained from Dr. Abraham R. Hollender, chairman, refresher course committee, department of otolaryngology, University of Illinois College of Medicine, 1853 West Polk Street, Chicago 12.

Beauty Products Company Ordered to Halt False Advertising.—The Federal Trade Commission on May 21 ordered the American Beauty Products Company to halt false advertising about the cure-all properties of certain vitamin preparations it sells in interstate commerce, according to the Chicago *Sun*. The company also was told to stop representing that any article is "free" when the recipient is required as a condition "to obtain the same to purchase some other article or render some service."

Course in Electroencephalography.—A two weeks course in electroencephalography is offered by the department of psychiatry of the University of Illinois College of Medicine under the supervision of Dr. and Mrs. Frederic A. Gibbs. It is intended primarily for medical officers in the armed forces, but applications will be accepted from others who have qualifications for undertaking such work. The course will begin June 11. Persons interested may address Dr. Gibbs at the University of Illinois, 912 South Wood Street, Chicago 12.

Alumni Dinner.—The Medical Division of Northwestern University Alumni Association will entertain the members of the graduating class, and faculty, at dinner to be given at the Furniture Club of America, 666 Lake Shore Drive, Chicago, June 11, at 6:30 o'clock. Guests of honor will include Franklyn B. Snyder, LL.D., president of the college; Fred D. Fagg Jr., LL.D., dean of the faculties; Dr. George H. Gardner, assistant dean of the medical school; Comdr. Walter G. Reddick (MC); Lieut. Col. Harold C. Lueth, M. C., and the members of the class of 1895. Commander Reddick will speak on "The Young Medical Officer in the Navy" and Colonel Lueth, "The Young Medical Officer Looks to the Future." A special invitation is extended to all Northwestern Medical Alumni. Because of existing food conditions, reservations for this dinner must be made at the Medical Alumni Office, Room 796, 303 East Chicago Avenue, Chicago, by June 8.

INDIANA

Dr. Judd Gives Commencement Address.—Dr. Walter H. Judd, congressman from the Fifth Minnesota District, gave the commencement address of Franklin College, Franklin, May 6, on "Building Tomorrow's World." A feature of the commencement was the presentation of the honorary degree of doctor of laws to Dr. Judd and that of doctor of science to Dr. Herbert F. Thurston, Indianapolis.

Membership of State Board of Health.—The membership of the Indiana State Board of Health now includes nine persons in accordance with a recently enacted bill. Members designated by Governor Ralph E. Gates are Dr. James L. Wyatt, Fort Wayne; Dr. Jacob T. Oliphant, Farmersburg, Dr. David R. Johns, East Chicago, and Howard Johnson, orchardist and businessman, Mooresville, who will serve four

year terms; Glenn L. Jenkins, Ph.D., dean of the School of Pharmacy, Purdue University, Lafayette, and R. E. Julian, veterinarian and serum producer, three year terms; Miss Mary Heckard, superintendent of nurses, James Whitcomb Riley Hospital for Children, Indianapolis, and W. B. Currie, Indianapolis, dentist, two year terms, and Don E. Bloodgood, head of the department of civil engineering, Purdue University, one year. On May 11 Dr. Johns was elected chairman of the board. Dr. Leroy E. Burney, regional director for the U. S. Public Health Service, New Orleans, was named state health commissioner and secretary of the board. Dr. Thurman B. Rice, Indianapolis, was reelected acting secretary and commissioner until July 1, when Dr. Burney will take over the office.

LOUISIANA

University News.—Dr. Peyton Rous, member, Rockefeller Institute for Medical Research, New York, addressed the students and faculty of the Louisiana State University School of Medicine, New Orleans, on "Present State of the Cancer Problem." Dr. Arild E. Hansen, professor of pediatrics, University of Texas Medical Branch, Galveston, spoke April 13 on "Some Phases of Lipid Metabolism" and the "Evaluation of the Nutritional State of the Child."

The Circle Chooses New Members.—Norman F. Conant, Ph.D., associate professor of bacteriology and mycology, Duke University School of Medicine, Durham, N. C., was the principal speaker at a recent meeting of the Circle, undergraduate honor scholastic society at Louisiana State University School of Medicine, New Orleans. Dr. Pierre Jorda Kahle, professor and director of the department of urology at the medical school, was elected an honorary member and Donald Duncan, Ph.D., professor of anatomy, was elected to membership on the faculty advisory committee of the Circle. New members from the junior class are David W. Aiken, Joe F. Simpson and Dorothy R. York, and those from the senior class include Walter J. Hollis, Edwin Byer, Harold J. Jacobs, William R. Scarborough and James C. Burns.

MASSACHUSETTS

Occupational Therapy Affiliation.—The affiliation of the Boston School of Occupational Therapy with Tufts College in the fall of 1945 completes total affiliation of the sixteen schools for occupational therapy in the United States with approved schools. There are seventeen approved occupational therapy schools, one of which is in Toronto.

Licenses Revoked.—The Massachusetts Board of Registration in Medicine announced the revocation of the license to practice medicine February 21 of Dr. Nathan Gaber, Boston, because of gross misconduct in the practice of his profession, as shown by collusion. At a meeting, March 16, the license of Capt. George J. J. Orlansky, M. C., was revoked on a similar charge.

Alumni Election.—Dr. Leon W. Crockett, Boston, was chosen president of the Alumni Association of Boston University School of Medicine May 11, succeeding Dr. Eleanor B. Ferguson-Howard, the first woman physician ever to head the association. Other officers include Drs. Roger M. Burgoyne, Winchester, and James E. Vance, Natick, vice presidents; Frank E. Barton, Boston, secretary, and Kenneth Christophe, Boston, treasurer. A feature of the reunion was the special meeting of the class of 1895, of which ten members are living.

Personal.—Dr. Derek E. Denny-Brown, professor of neurology, Harvard Medical School, Boston, has been granted a leave of absence to return to active military duty as a brigadier general with the British forces in India and Southeast Asia. In 1941, after two years of service in the field, he was temporarily released by the British army to carry on research and teaching in the United States, according to *Science*.——Alice M. Boring, Ph.D., associate in anatomy at Columbia University College of Physicians and Surgeons, has been appointed visiting professor of zoology at Mount Holyoke College, South Hadley. For many years professor of biology at the Chinese University of Yenching, Dr. Boring returned to this country last year after being interned seven months by the Japanese. ——Irwin W. Sizer, Ph.D., associate professor of physiology at the Massachusetts Institute of Technology, Cambridge, has been awarded a grant of $5,000 by the Eli Lilly pharmaceutical company for the continuation of his studies on the action of enzymes on the irritant principles of poison ivy and related plants.

Practice of Anesthesiology.—The hospital section of the postwar planning committee of the New England Society of Anesthesiology would like to hear from physicians who are interested in the peacetime practice of anesthesiology in New England. This information will be made available to persons interested in obtaining the services of an anesthesiologist in their individual surgical practice, group or hospital in New England. It is felt that the collection and dissemination of this information may facilitate the proper relocation of anesthesiologists now in the service when they return to civilian practice. The following information is desired from those interested: age, medical school, year of graduation, internship (year and hospital), training in anesthesiology (in detail), give length and type of training, chief of service, activity and specialty after completion of training, military experience in anesthesia, publications, membership in medical societies, present address and a permanent address. The information should be addressed to Dr. Morris J. Nicholson, chairman of the postwar planning committee, 605 Commonwealth Avenue, Boston 15. Other members of the committee are Drs. Jacob Fine and Signey C. Wiggin, Boston.

MICHIGAN

Status of Hospital Commission Changed.—The state hospital commission will be known as the department of mental health, in accordance with a recently enacted law which becomes effective September 7. The act further sets up a five member, policy determining commission by appointment of the governor to make policies and adopt rules and regulations governing the operation of the department. Under the law a director of mental health will be selected by the commission and the governor for a six year term, the director to be a physician legally registered in the state of Michigan with at least ten years' experience as a psychiatrist in the treatment of mental diseases and the administration of mental hospitals and mental health programs. The administration of the department is to be divided into three divisions: business administration, hospitals and mental hygiene. The head of one of the three divisions will be designated as deputy director. The director of the department of health will appoint, subject to approval of the commission, a head for each division, a medical superintendent for each state hospital and state home and training school, who is to be a physician legally registered in the state with at least three years of experience in the treatment of the mentally afflicted, and a director for each child guidance clinic. The department is to be housed in suitable offices in Lansing. With the creation of the new department of health the old state hospital commission will be abolished.

MISSOURI

Joseph Erlanger Honored.—Dr. Joseph Erlanger, professor of physiology, Washington University School of Medicine, St. Louis, and 1944 joint winner of the Nobel Prize, has been awarded the certificate of merit and medal for distinguished service of the St. Louis Medical Society because "his contributions to fundamental knowledge of the cardiovascular and nervous system and to methods of physiological investigation, his excellence as a teacher and his devotion to the furtherance of medical research have strengthened the hand and augmented the skill and discernment of present and future practitioners of medicine."

NEW YORK

Licenses Reinstated.—The licenses to practice medicine of Drs. Michael James Pietaro, Brooklyn, and August C. Schwenk, New York, have been reinstated.

Basil MacLean Named Professor of Hospital Administration.—As a step toward eventual organization of a department of hospital administration in the University of Rochester School of Medicine and Dentistry, Dr. Basil C. MacLean, director of Strong Memorial Hospital, has been appointed professor of hospital administration, a newly created position. Dr. MacLean has been director of the Strong Memorial Hospital since 1935, returning to the position last September after an absence of more than a year while he served in Washington as a lieutenant colonel in the medical corps of the army as consultant in the surgeon general's office. Dr. MacLean is also in charge of a ten member commission appointed by Governor Dewey to draft a program providing medical care for the state's needy to make recommendations for action by the state legislature.

Alleged Abortion Mill.—On April 27 three alleged operators of an Irondequoit (Rochester) abortion mill were being held in Monroe County jail pending grand jury action. All three were charged with abortion and remanded to jail in lieu of $25,000 bail each. Newspapers reported that the police estimated more than $100,000 had been collected from more than 700 young women patients. The abortion ring was said to be operating at 3731 St. Paul Boulevard, Irondequoit, for more than a year and a half, where investigators found a completely equipped clinical room with operating table. Investigation of the alleged abortion ring began after several reports from a hospital of patients admitted suffering from after-effects of illegal operations. Fees generally ranged from $75 to $150, while some ranged as high as $500. One of the so-called operators, Bennett Mistrator, who was said to have performed the operations, is said to be listed in the suburban directory as a salesman.

New York City

Proposed Addition to St. Vincent's Hospital.—Plans for a sixteen story addition to St. Vincent's Hospital as a memorial to Alfred E. Smith were announced May 13. The addition will replace an old five story unit of the hospital. The estimated cost is three million dollars, to be raised by public subscriptions soon to be sought by the hospital's advisory board, according to the New York *Times*. The memorial wing will give the hospital 250 beds and provide other accommodations.

Blue Cross Extends Benefits.—In a statement May 8, Louis H. Pink, president of the Associated Hospital Service, announced that an extended program of benefits of hospitalization would be made available to members of the Blue Cross Plan. The added services would double the number of days during which members would receive hospitalization at reduced costs. At present the plan offers twenty-one days of semiprivate hospitalization without cost and ninety days of such care at half cost discount rates each time subscribers are hospitalized for a different ailment. Under the new setup the discount coverage is increased to one hundred and eighty days, according to the New York *Times*.

Postgraduate Medical School and Hospital Seek Funds.—A campaign with an immediate goal of five million dollars and an eventual goal of fifteen million dollars for an expansion program at the New York Post-Graduate Medical School and Hospital, Columbia University, was announced at the seventieth anniversary dinner of the school, May 9. The expansion program contemplates a new clinic, classroom and laboratory building, to be erected on the land adjacent to the present plant at an estimated cost of $1,500,000 and holding an endowment of $3,500,000 for staff and research expense. Other projects include a private pavilion of 200 beds, a new medical school building and a new hospital unit for ward beds to replace Roosa Building, opened for service in 1894. The entire project was suggested as a memorial to members of the profession who have performed in the current conflict.

Committee of Teachers Sues School and Health Boards.—Challenging the right of the board of education to compel teachers to undergo x-ray examinations of the chest for tuberculosis, the Joint Committee of Teachers Organizations, representing New York City's 30,000 school employees, started a law suit May 7 against the school board and the board of health to force a reprisal of the regulation, according to the New York *Times*. The complaint declares that the board of health does not have the authority to adopt the policy requiring all teachers and school employees who come in contact with pupils to take a chest examination every two years. If found to be infected with "active tuberculosis" the teachers are to be excluded from the school, although the board of education permits these teachers to take a leave of absence with part pay while recuperating. It was stated that the school staff resents the board's action and feels that it is an unjust attack on the teaching profession. It was contended that a present law giving to principals the right to require teachers to appear before the medical department for a physical examination if there is any suspicion of ill health should be sufficient to cover teachers who may have tuberculosis. Mrs. May Andres Healy, chairman of the joint committee, in a statement to the press said "We have not heard that tuberculosis is prevalent among teachers. This regulation will frighten the public and regiment the teachers. No other group in the city has this type of examination. Certainly our teachers are intelligent enough to go to a doctor when they are ill; they do not need to have this embarrassing situation inflicted upon them."

OKLAHOMA

Activities on Medical Faculty.—Dr. Hubert Eugene Doudna, professor of clinical anesthesiology, University of Oklahoma School of Medicine, Oklahoma City, has been granted a leave of absence for active duty in the Navy. Dr. Charles R. Rayburn, Norman, on leave with the Army since June 15, 1942, has returned to his position as professor of mental diseases.

State Medical Election.—Dr. Louis C. Kuyrkendall, McAlester, is the new president-elect of the Oklahoma State Medical Association. Dr. Victor C. Tisdal, Elk City, assumed the office of president at a meeting of the house of delegates on April 22. Dr. Ralph A. McGill, Tulsa, is vice president and Dr. Lewis J. Moorman, Oklahoma City, continues as secretary-treasurer and editor of the *Journal*.

Endowment for Ophthalmology.—Dr. and Mrs. Samuel J. Bradfield have established an endowment fund for the library of the Tulsa County Medical Society to be known as the Dr. Albert W. Roth Endowment for Ophthalmology and which honors the physician who was an honorary member of the Tulsa County Medical Society and served in 1917 as its president. Dr. Roth was also a founder and president of the Tulsa Public Health Association. He died March 17.

PENNSYLVANIA

Society News.—Dr. Herbert T. Kelly, Philadelphia, addressed the Centre County Medical Society at Nittany Lion, State College, May 10, on "Convalescent Care and Postoperative Management."

Philadelphia

Christian Febiger Dies.—Christian Febiger, a member of the firm of Lea & Febiger, medical publishers, died May 12.

Course on Venereal Diseases.—The department of public health and preventive medicine, University of Pennsylvania School of Medicine, opened a course May 22 on the control of venereal diseases under the direction of Dr. John H. Stokes. The course will continue until June 30 and carries two units of credit for those working for a graduate academic or public health degree.

Personal.—Dr. Francis D. Patterson has been appointed to the advisory health board of the state of Pennsylvania. Dr. Alexander H. Stewart, Harrisburg, secretary of the state department of health, is chairman of the board, and other members consist of Dr. Thomas Palmer Tredway, Erie, Pa.; Dr. James D. Lewis, Scranton, Pa.; Dr. Joseph Scattergood Jr., West Chester, Pa.; Mr. Arch W. Nance, C.E., Pittsburgh, and Dr. David W. Thomas, Lock Haven, Pa.—Dr. and Mrs. Thomas Ellison recently celebrated their fiftieth wedding anniversary.

Dr. Cantarow Named Professor of Physiological Chemistry.—Dr. Abraham Cantarow, associate professor of medicine at the Jefferson Medical College of Philadelphia and chemist to the Jefferson Medical College Hospital, has been appointed professor of physiologic chemistry, succeeding George R. Bancroft, Ph.D., who will retire at the end of the school term in June. Dr. Cantarow graduated at Jefferson in 1924 and became the first resident chemist at the hospital, where he subsequently served his internship and as assistant demonstrator in medicine and research fellow in the department of diseases of the chest.

Pittsburgh

Special Society Election.—At a recent meeting of the Pittsburgh Roentgen Society the following officers were elected for the following year: Drs. Reuben G. Alley, president; Robert Meader, vice president, and Lester M. J. Freedman, secretary-treasurer.

Hospital Changes Name.—The name of the Western State Psychiatric Hospital has been changed by action of the legislature to Western State Psychiatric Institute and Clinic. The change, long under consideration, was brought about to emphasize the important functions of training, teaching and research and the operation of the mental health clinic. In cooperation with the University of Pittsburgh, instruction is given to students in medicine, nursing, psychology, social service and dentistry. Six junior and six senior residencies in psychiatry are available. Junior positions offer opportunities in clinical work and teaching. Senior positions require previous experience in psychiatry; this work is largely confined to the care and treatment of outpatients. Additional information may be obtained from Dr. Grosvenor B. Pearson, director of the Western State Psychiatric Institute and Clinic, O'Hara and Desoto streets.

TENNESSEE

The Haggard Lecture.—Dr. Rustin McIntosh, professor of pediatrics, Columbia University College of Physicians and Surgeons, New York, delivered the annual Haggard Memorial Lecture at the Vanderbilt University School of Medicine, Nashville, April 27, on "Congenital Malformation Causing Obstructive Phenomena." The lecture is sponsored by the student chapter of Alpha Kappa Kappa.

Chapter Meeting of International College of Surgeons.—The Tennessee Guild of the U. S. Chapter of the International College of Surgeons and the Knox County Medical Society, Knoxville, will cooperate in a meeting June 8 at the Andrew Johnson Hotel for the following program:

Dr. Custis Lee Hall, Washington, D. C., Stenosing Tenosynovitis of the Wrist.
Dr. Robert L. Sanders, Memphis, Surgical Complications of Duodenal Ulcer.
Dr. Albert A. Berg, New York, Prevention of Recurrent Ulcers After Subtotal Gastrectomy by Vagus Section.
Dr. William Milton Adams, Memphis, Early Treatment of Extensive Facial Injuries.
Dr. William Seaman Bainbridge, New York, Surgical Emergencies.
Dr. Desiderio Roman, Philadelphia, Lingual Goiter.
Dr. Max Thorek, Chicago, Surgical Plagiarism: Its Etiology, Manifestations and Cure.
Dr. Moses Behrend, Philadelphia, Surgery of the Common Bile Duct.
Dr. Gilbert F. Douglas, Birmingham, Conditions and Diseases Incident to the Menopause.
Dr. Lloyd F. Craver, New York, Hodgkin's Disease.
Dr. Watson B. Morris, Springfield, N. J., Office Gynecology.

WEST VIRGINIA

Health Department Activities.—The Public Health Council has entered an order separating the bureau of industrial hygiene from the division of sanitary engineering. Similar action has separated the bureau of dental hygiene of the state health department from the division of maternal and child hygiene, setting it up as a separate unit. The new dental bureau will be under the direct supervision of Dr. John E. Offner, Weston, state health commissioner; two dental counselors will carry out the work now done by a dental consultant.

State Medical Election.—Dr. Andrew E. Amick, Charleston, was elected president of the West Virginia State Medical Association at a meeting of the house of delegates in Clarksburg, May 14. Dr. Blonda S. Brake, Clarksburg, and Dr. James B. Thompson, Oak Hill, were named as vice presidents, and Dr. Thomas M. Barber, Charleston, was reelected treasurer. Dr. Ivan Fawcett, Wheeling, and Dr. James L. Wade, Parkersburg, were reelected as American Medical Association delegate and alternate, respectively. At this meeting, which was held in lieu of the 78th annual meeting, the president was authorized to appoint a standing committee on tuberculosis and a special committee on relocation and reestablishment of doctors returning from military service. The house also adopted an amendment to the constitution increasing annual dues from $10 to $15, effective Jan. 1, 1946. An amendment to the constitution was proposed which provides for the election, with the approval of the council, of affiliate members of component societies who, although doctors of medicine, cannot qualify for licensure in West Virginia. The amendment will be acted on at the annual meeting, which will be held at Huntington in 1946.

ALASKA

Department of Health Created.—On March 21 the legislature of the Territory of Alaska approved an act providing for the establishment of a department of health, charged with the duty of administering laws and regulations relating to the promotion and protection of the public health, control of communicable diseases, programs for the improvement of maternal and child health, care of crippled children, hospitalization of the tuberculous, and such other duties as may be conferred on it by law. The act provides for a board of health within the department of health consisting of the governor and four members, one from each judicial division of the Territory of Alaska appointed by the governor, one of whom shall be a member of the Alaska Territorial Medical Association. All will be subject to approval of the senate and house, and each is to serve for four years. The board will appoint a commissioner of health who will be chief executive of the health department, appointed on a full time status for a term of five years and eligible for license under the medical practice laws of Alaska. Members of the new board appointed by the governor are Dr. Dwight L. Cramer, Ketchikan; Mrs. Katherine Kehoe, Nome; Rev. R. Rolland Armstrong, Anchorage, and Mr. George Preston Sr., Fairbanks. Previously the legislature had been willing only to create the office of commissioner of health. On May 17 the board had not yet met or organized, nor had it selected the new commissioner of health.

GENERAL

Health Council Reelects Officers.—The National Health Council has reelected Mrs. Eleanor Brown Merrill, executive director of the National Society for the Prevention of Blindness, New York, as president. Other officers who were reelected include Dr. Charles Walter Clarke, executive director of the American Social Hygiene Association, New York, vice president; Maurice A. Bigelow, Sc.D., New York, former president of the American Eugenics Society, secretary, and Dr. William F. Snow, general director of the American Social Hygiene Association, treasurer. The National Health Council, with headquarters at 1790 Broadway, New York 19, is a clearing house of twenty-one voluntary health organizations.

Grant for Cancer Research.—The Rockefeller Foundation through its Division of Medical Sciences has given $282,000 to the Roscoe B. Jackson Memorial Laboratory, Bar Harbor, Maine, for the study of "the genetic factors in intelligence and emotion in mammals" in the hope of learning more about human beings as they are born and the way they grow up. According to an announcement in *Science News Letter* the main reason for using dogs in the early part of the project is that genetic experiments require pure strains differing as much as possible in the characteristics it is proposed to study. The *News Letter* states that Hamilton Farm, consisting of a 58 acre estate, recently given to the laboratory and located just outside of Bar Harbor, will be used for the study.

The Doctor Fights.—A radio series of coast broadcasts over the Columbia Broadcasting System entitled "The Doctor Fights" will begin Tuesday, June 5. Motion picture stars will participate in the dramatization of such events as the devotion to duty of Major Livingston Pope Noell Jr., M. C., the physician who elected to stay with the litter cases on Bataan when the hospital unit and all the nurses were evacuated to Corregidor, the heroic three days in July last year, when Capt. James E. T. Hopkins, M. C., treated 80 casualties during the battle for the Munda air strip on the Solomon Islands, and other similar case histories from actual service files. The broadcasts are being presented by Schenley Laboratories, Inc., and will consist of thirteen dramatizations. Whenever possible the programs will be cut in from Washington and other points to introduce the doctors of medicine whose stories are being dramatized.

Aid to China.—Thirty medical and health experts will go to China to train personnel in medical centers to be established by the Chinese government, Herbert H. Lehman, director general of the United Nations Relief and Rehabilitation Administration, announced May 10. Essential supplies will also be furnished by UNRRA to equip centers in Chungking and Chengtu, and later in Kweiyang, Nanking and Peiping. It was said that in the coming months 90,000 pounds of medical supplies would be shipped for the project. According to the New York *Times*, one of China's most serious needs is said to be skilled medical and technical personnel, estimates showing that there is only 1 doctor in China for every 40,000 persons and 1 hospital bed for every 10,000. Experts of the UNRRA mission, which forms part of the general program of rehabilitation for China, will be recruited from the United States, Great Britain, Australia and Canada.

Maternity Leaves Recommended.—Recommendations for maternity clauses in union contracts were issued April 30 by the Women's Bureau of the U. S. Department of Labor in the first of a series of leaflets resulting from a survey of ninety-two midwestern war plants in Illinois, Indiana and Wisconsin. The survey showed that only five plants had union contracts carrying maternity leave provisions. More than two thirds of the contracts had provisions for illness which was sometimes construed as covering maternity leave. In most local unions no attention, however, had been paid to this question and in some plants women were discharged when their pregnancy became known, according to the New York *Times*. The Women's Bureau claims that a maternity clause is needed in the union contract for the following reasons:

To protect the health of the mother and children.
To protect the expectant mother against discharge and to protect her right to return to her job.
To see that women retained their seniority rights and were not penalized when they have babies.
To see that there was a good maternity policy in every plant where women are employed.

CORRECTION

Marriages.—In the marriage announcement of Carroll R. Olson to Miss Thelma Olson, THE JOURNAL, April 28, page 1143, the bride's name should have appeared Miss Thelma Cousin.

Foreign Letters

LONDON

(From Our Regular Correspondent)

April 28, 1945.

London's Last Ordeal

With the end of the last form of "frightfulness" practiced on London—the rocket bomb, which was fired from the continent and reached us after traversing the stratosphere—the government is now able to publish details. The total number of rocket bombs which reached this country was 1,050. The total casualties were 2,754 killed and 6,523 seriously wounded. The first rocket fell on the evening of Sept. 8, 1944 at Chiswick, doing considerable damage. One of the first to fall on London was at Brentford, where eight houses were destroyed and fifty damaged by the blast. Two people were killed and ten seriously injured. The rocket attack reached its height during a week in February, when seventy-one fell on southern England. Totals of fifty or sixty rockets a week were common in February and March, many of them on London. The highest number in twenty-four hours was seventeen. Then came the Canadians' advance into the northern part of the Netherlands, the overrunning of rocket sites and the end to one of the most diabolic forms of attack on a civilian population. The last rocket fell on March 27 at Orpington, killing 1 person and injuring 23.

Among the worst incidents was the fall of a rocket on Woolworth's store in southeastern London during the lunch hour rush, when the pavements as well as the store were crowded with women and children. One hundred and sixty were killed and 108 injured. In March a rocket reduced two blocks of flats to rubble in eastern London, killing 134 and seriously injuring 49. One fell on Farringdon market in March, when the stalls were crowded with shoppers; 110 were killed and 123 seriously injured. In these raids thirty-five hospitals were hit. Seven American soldiers were killed when a rocket fell in the west end of London.

A New Insecticide

In a lecture to the Society of Chemical Industry, Dr. Roland Slade of Imperial Chemical Industries announced the discovery of a remarkable new insecticide with a wide range of uses, gammexane, which is the gamma isomer of benzene hexachloride ($C_6H_6Cl_6$). This was isolated early in 1943 and was found to be more toxic to weevils than any substance previously tested. There is every indication that it is much more toxic in locust baits than anything used heretofore. It has numerous medical, veterinary and agricultural uses. Experiments in the field against wireworm have led to the hope that we have found at last a means of fighting this pest, which causes the failure of so many farmers' crops in Britain. Gammexane has proved highly toxic to lice and fleas. Dusts, sprays and paints have been used experimentally on the surfaces of rooms and rendered them toxic to any flies that walked over them.

Surgeon Attacks Method of Cancer Research

At the Medical Society of St. Mary's Hospital a surgeon, Mr. D. C. L. Fitzwilliams, said that an outlay of $5,000,000 by the British Empire Cancer Campaign had shown only one important discovery, that of diethylstilbestrol by Professor Dodds. No one would wish to underrate this, but this, with the addition of something in trades cancer and carcinogenic agents, was hardly full value for time and money. He attributed this failure to the haphazard and uncoordinated nature of British research. He described a scheme in which five hundred research workers under ten directors and one superdirector would deal with all aspects of the problem.

Subsequent speakers unanimously disagreed with him and described his scheme by the expressions "dictatorship," "German" and hence "not British." Professor Dodds said that Pasteur, with his academic qualifications at the time, would hardly have been employed by "the director of a suppuration campaign." But he took some of the sting out of his allegory by suggesting that energy and funds should be expended not on research into a specific disease but into general biochemistry and pathology, which may confidently be expected to yield information of practical as well as theoretical value.

Norwegian Psychiatrist Murdered by the Germans

The *British Medical Journal* of April 14 contains the obituary of Dr. Haakon Saethre, who was head of the psychiatric department of Oslo City Hospital and through his excellent clinical work and administrative abilities made his clinic one of the most inspiring in Norway. His work on oxycephaly, disseminated sclerosis, dementia paralytica and other subjects is classic in neurologic literature. He was official Norwegian delegate to several international congresses and president of the Inter-Scandinavian Congress of Psychiatry held in Oslo in 1938. He devoted much energy to popularizing the general principles of mental hygiene. On February 9 he was arrested with several Norwegian patriots as hostages. They were immediately sentenced to death by a German summary court martial as a reprisal for the killing of a Quisling police chief the day before by Norwegian Home forces.

The Campaign Against Leprosy

The British Empire Leprosy Relief Association held its twenty-first anniversary meeting in London. The lord mayor said that the association had done remarkable work in combating the scourge of leprosy throughout the empire. The meeting inaugurated a campaign to raise $1,050,000, representing $50,000 for every year of the association's existence, in an intensified effort to abolish leprosy within the empire, in which there are 2,000,000 sufferers. In the absence of the secretary of state for the colonies, his representative said that the Colonial Office had benefited by the collaboration of the association, together with that of the missionary societies and Toc H, but the measures so far taken were inadequate, notwithstanding what had been done.

Marriages

PAUL ALEXANDER BENDIX, Mount Vernon, N. Y., to Lieut. Frances Nantes Briscoe, Army Nurse Corps, at Charleston, S. C., March 28.

ORVILLE JAMES LIGHTHIZER, Ashtabula, Ohio, to Miss Michaelene Bogan of Lexington, Ky., May 24.

GEORGE E. FELKNOR Jr., Meridian, Miss., to Miss Marion C. Starts of New Orleans, Dec. 29, 1944.

JOHN PATRICK MURPHY, Boston, to Miss Elizabeth Ann Lehiff of Arlington, Mass., April 7.

FORDE ANDERSON McIVER to Miss Ruth Raymond Huegel, both of Madison, Wis., April 14.

EUGENE LAWSON ARMSTRONG to Miss Bernice Ehri Collins, both of Los Angeles, February 8.

JAMES W. BARRETT to Miss Margaret Mary Williette, both of East Orange, N. J., April 12.

CHARLES D. COOK, Minneapolis, to Miss Sheila Gamble of Brookline, Mass., March 10.

JULIAN PETER KRAKOWSKI, Waterloo, Ill., to Miss Fern Zinser of El Paso, April 14.

HOWARD S. BRANIN to Mrs. Lilyan B. Murphy, both of Millville, N. J., March 18.

DAVID McCULLOUGH, Kerrville, Texas, to Miss Mary Myers of Electra, February 21.

BEN HILL CLIFTON to Miss Faye Hollis, both of Atlanta, Ga., April 7.

Deaths

Paul August Teschner ⊕ assistant director, Bureau of Health Education, American Medical Association, died at his home in Elmhurst, May 25, aged 48, of chronic valvular heart disease with acute decompensation.

Dr. Teschner received his education at the Washington High School, Milwaukee, the Milwaukee Normal School and the University of Wisconsin. He graduated in 1924 at the Marquette University School of Medicine, Milwaukee, completed his internship at the Northwestern Branch, National Home for Disabled Volunteer Soldiers, National Home, Wis., and subsequently practiced medicine in Gillette and Cecil, Wis. In 1926 he became a member of the medical staff of the Wisconsin Anti-Tuberculosis Association, serving as examiner and consulting physician. In 1939 he joined the staff of the American Medical Association as assistant director of the Bureau of Health and Public Instruction, then a newly created position. In this capacity he had lectured before various groups throughout the country and was well known to lay agencies interested in health activities, carrying practically all the question and answer correspondence with the lay public, one of the most important functions of the Bureau.

Dr. Teschner was a member of the editorial board of *Hygeia*, assistant in charge of the American Medical Association radio program on NBC network and other stations, and a member of the first aid medical advisory committee of the Chicago chapter, American Red Cross. He was the co-author of the Workbook on Health coordinated with the American Medical Association radio program Your Health and was an extensive contributor of articles on health subjects to magazines.

Abraham Rudy ⊕ Boston; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, Germany, 1923; instructor in medicine at Tufts College Medical School; member of the Greater Boston Medical Society, Boston Society of Biologists, New England Heart Association, Association for the Study of Internal Secretions and American Diabetes Association; fellow of the American College of Physicians; associate in medicine at the Beth Israel Hospital, where he served as chief of the diabetic clinic, which he helped to organize; from 1926 to 1928 assistant in medicine at the Mount Sinai Hospital in New York; visiting physician and consultant in diabetes at the Jewish Tuberculosis Sanatorium, Rutland, and at the Jewish Memorial Hospital; author of the "Practical Handbook for Diabetic Patients" and of the "Simplified Diabetic Manual"; his authority was recognized by the New York Diabetes Association, which invited him to write two of the Fundamental Concepts in the Treatment of Diabetes Mellitus and Its Complications; died February 19, aged 49, of pulmonary neoplasm.

Frederic Russell Calkins ⊕ Watertown, N. Y.; Bellevue Hospital Medical College, New York, 1894; fellow of the American College of Surgeons; twice president of the Jefferson County Medical Society; at one time county physician and county coroner; served on the local medical examining board during World War I; formerly affiliated with the local National Guard; vice president and director of the Y. M. C. A.; served as director of the chamber of commerce and the Jefferson National Bank; for many years chief surgeon at Mercy Hospital and the House of the Good Samaritan, where he died February 24, aged 73, of arteriosclerosis and heart failure.

Gustav Adolf Pudor, Portland, Maine; Harvard Medical School, Boston, 1892; honorary member of the Maine Medical Association and member of the American Medical Association; formerly professor of dermatology at the Bowdoin Medical School; fellow of the American College of Physicians; served as captain in the Base Hospital at Camp Devens during World War I; captain, medical reserve corps, U. S. Army, not on active duty; on the staffs of the Maine School for Deaf, Maine General Hospital and Children's Hospital; affiliated with the venereal disease clinic at Portland City Dispensary; died March 7, aged 80, of arteriosclerotic heart disease.

Rosario Gori, Brookline, Mass.; Regia Università degli Studi di Roma, Facoltà di Medicina e Chirurgia, Italy, 1925; served during World War I; at one time on the staff of the Misericordia Hospital in Ottawa, Ont.; Italian consular general in western Massachusetts until all Italian officials were returned to that country following this nation's entry into World War II; at the time of his death was serving as medical officer, under the civilian mobilizer appointed by the allied military government, in Belsito, province of Cosenza, Italy, where he died February 1, aged 47, of heart disease.

William P. E. Wyse, Pikesville, Md.; University of Maryland School of Medicine, Baltimore, 1886; member of the American Medical Association; deputy medical examiner for Baltimore County; president of the board of governors of the Rosewood State Training School, Owings Mills; consultant on the staff of the Mount Hope Retreat, Baltimore; formerly surgeon to the Maryland Line Confederate Soldiers' Home; died in the Union Memorial Hospital, Baltimore, March 12, aged 78, of injuries received in an automobile accident.

William Hunter Arnold, Thompsons Station, Tenn.; Hospital College of Medicine, Louisville, Ky., 1876; died February 10, aged 89.

Jerry Clark Bliss, Denver; Cincinnati College of Medicine and Surgery, 1875; Civil War veteran; died January 25, aged 99, of purulent cystitis and cerebral hemorrhage.

William B. Boggess, Pittsburgh; Hahnemann Medical College and Hospital of Philadelphia, 1897; died in the Shadyside Hospital January 12, aged 71, of congestive and hypertensive heart disease.

Ralph Childs Bowen ⊕ Cumberland, Md.; University of Maryland School of Medicine, Baltimore, 1907; died February 28, aged 60, of hypertension and chronic myocarditis.

Elizabeth Annastatia Brackett, Malden, Mass.; Boston University School of Medicine, 1891; died February 16, aged 88, of generalized arteriosclerosis.

Charles Augustus Brown, Hopkinton, Iowa; State University of Iowa College of Homeopathic Medicine, Iowa City, 1891; died February 5, aged 77, of chronic myocarditis.

Joseph Addison Buckwalter ⊕ Royersford, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1904; died January 26, aged 64, of coronary occlusion and diabetes mellitus.

H. D. Carson, Union Point, Ga.; University of the South Medical Department, Sewanee, Tenn., 1899; city health officer; local surgeon for the Georgia Railroad; died in the Athens General Hospital, Athens, March 28, aged 72, of carcinoma of the pancreas.

Frederick Henry Carter, Derby, Vt.; College of Physicians and Surgeons, Boston, 1907; member of the American Medical Association; health officer of the town of Derby; died in the Orleans County Memorial Hospital, Newport, April 3, aged 66, of gastric hemorrhages.

Clarence Marmaduke Casselberry ⊕ Newton, Mass.; University of Pennsylvania Department of Medicine, Philadelphia, 1897; on the staff of the Boston Dispensary; died February 23, aged 69, of carcinomatosis.

Samuel M. Clark, Knoxville, Tenn.; Meharry Medical College, Nashville, 1910; on the staff of the Knoxville General Hospital; died March 11, aged 62, of coronary occlusion.

Albert Crocker Cobb ⊕ Marion, Mass.; Albany Medical College, 1892; an Affiliate Fellow of the American Medical Association; school physician for many years; died March 21, aged 76, of anemia and uremia.

Basil Loren Connelly ⊕ Detroit; Western Reserve University School of Medicine, Cleveland, 1920; fellow of the American College of Surgeons; served on the staffs of the East Side General Hospital, St. Mary's Hospital, Woman's Hospital, Florence Crittenton Hospital, Mount Carmel Mercy Hospital and Grace Hospital, where he died April 1, aged 51, of coronary thrombosis.

Howard Russell Cooder ⊕ Los Angeles; McGill University Faculty of Medicine, Montreal, Que., Canada, 1921; assistant professor of pediatrics, College of Medical Evangelists; chairman of the pediatric section, California Medical Association, and secretary-treasurer from 1934 to 1936 of the Southwestern Pediatric Society; interned at St. Louis Children's Hospital and the Children's Memorial Hospital in Chicago; on the staff of the Children's Hospital; died March 26, aged 58, of Hodgkin's disease.

Daniel Joseph Daly, New York; Baltimore Medical College, 1905; member of the American Medical Association; died in Bellevue Hospital February 10, aged 64.

James Joseph Daly, Decorah, Iowa; Northwestern University Medical School, Chicago, 1898; examiner for the local draft board; served during World War I; died February 20, aged 75, of coronary thrombosis.

Charles Frederick Daniel, Tiffin, Ohio; Starling Medical College, Columbus, 1907; member of the American Medical Association; on the staff of the Mercy Hospital, where he died March 31, aged 65, of cerebral hemorrhage.

Roy Adelbert Daniels, Melrose, Mass.; (licensed in Massachusetts in 1895); died February 3, aged 70, of heart disease.

Wilbur Fiske David, Marshalltown, Iowa; the Hahnemann Medical College and Hospital, Chicago, 1881; died March 25, aged 85, of cerebral hemorrhage.

Frederick Detlefsen ⊕ Chicago; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, Germany, 1890; died in the Alexian Brothers Hospital April 5, aged 83, of chronic myocarditis and prostatic hypertrophy.

James Francis Donahue, Philadelphia; Medico-Chirurgical College of Philadelphia, 1902; died January 13, aged 77, of asthma and cardiac dilatation.

Ross May Fisher ⊕ Syracuse, N. Y.; Syracuse University College of Medicine, 1906; for many years on the staff of the Crouse-Irving Hospital; died February 4, aged 63, of aplastic anemia and leukemia.

William Henry Foster, St. Louis; St. Louis University School of Medicine, 1908; died in the Missouri Baptist Hospital April 1, aged 75, of congestive heart disease and myocarditis.

Thomas B. Fowler, Springville, N. Y.; Medical College of Ohio, Cincinnati, 1880; past president of the village board of education; a founder and director of Chaffee Hospital, where he died March 31, aged 89, of uremia caused by nephritis.

William Clarkson Freeman, Waco, Texas; Trinity Medical College, Toronto, Ont., Canada, 1876; died March 3, aged 90, of senility.

William M. Gibson, Nashville, Ark.; Memphis (Tenn.) Hospital Medical College, 1904; died January 10, aged 75, of arteriosclerosis.

Albert Arthur Gorbold, Ross, Ohio; Miami Medical College, Cincinnati, 1897; died in the Fort Hamilton Hospital, Hamilton, March 1, aged 75, of pernicious anemia.

Ruth Pierce Guilder, Boston; University of Illinois College of Medicine, Chicago, 1922; served as research fellow in otology at Harvard Medical School and the Massachusetts Eye and Ear Infirmary, where she had been affiliated with the Winthrop Foundation for the Study of Deafness; died February 12, aged 56.

Clarence Evans Johnson, Philadelphia; Southern Medical College, Atlanta, 1891; for many years represented Mead Johnson & Company of Evansville, Ind.; formerly employed by the Charles H. Phillips Chemical Company of New York; died while on a vacation in St. Petersburg, Fla., March 13, aged 70, of cerebral hemorrhage.

William Franklin Keim ⊕ Newark, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1899; member of the American Academy of Ophthalmology and Otolaryngology; on the staffs of the Hospital of St. Barnabas and for Women and Children, Newark Memorial and Presbyterian hospitals; died March 7, aged 76, of carcinoma of the stomach.

Hilda Kinkead, Madison, N. J.; Woman's Medical College of Pennsylvania, Philadelphia, 1935; diplomate of the National Board of Medical Examiners; member of the American Medical Association; interned at the Medical Center of Jersey City; served a residency at the Overlook Hospital in Summit and the New York Infirmary for Women and Children in New York; died in the Memorial Hospital, Morristown, March 19, aged 34, of an accidental overdose of barbituric acid.

Harry Van Kitzmiller, Wray, Colo.; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1905; for many years health officer of Yuma County; died March 14, aged 66, of cerebral hemorrhage.

Franz F. Lyon, Patchogue, N. Y.; Albert-Ludwigs Universität Medizinische Fakultät, Freiburg, Baden, Germany, 1912; member of the American Medical Association; died February 16, aged 57, of cerebral hemorrhage and hypertension.

Albert Sidney Maddox, Asbury Park, N. J.; Bellevue Hospital Medical College, New York, 1890; member of the American Medical Association and the Medical Society of the State of New York; died March 3, aged 78, of coronary occlusion.

Ervin McElroy, Rockaway, N. J.; Jefferson Medical College of Philadelphia, 1922; member of the American Medical Association; fellow of the American College of Surgeons; interned at the Newark City Hospital, Newark; served as school physician and as president of the board of health; member of Selective Service Board number five and of the Morris County Mosquito Commission; on the staff of the Dover (N. J.) General Hospital; died March 18, aged 47, of coronary thrombosis.

Samuel B. McMillan, Frisco City, Ala.; Atlanta College of Physicians and Surgeons, 1902; member of the American Medical Association; died January 6, aged 66, of cerebral hemorrhage.

John Henry Merrick ⊕ Glenwood, Iowa; McGill University Faculty of Medicine, Montreal, Que., Canada, 1895; since July 1944 staff physician at the Glenwood State School; died April 15, aged 72, of lung abscess following pneumonia.

Armand Normandin ⊕ Laconia, N. H.; M.B. in 1909 and M.D. in 1911, School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal; medical examiner for the draft board; died February 14, aged 57, of coronary thrombosis.

Robert Earl Patterson ⊕ New York; McGill University Faculty of Medicine, Montreal, Que., Canada, 1921; died February 11, aged 49, of coronary thrombosis.

Stanley Earl Patterson, Mandan, N. D.; University of Manitoba Faculty of Medicine, Winnipeg, Man., Canada, 1928; died February 6, aged 43, of cirrhosis of the liver.

Carlin Philips, New York; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1897; served during World War I and with the U. S. Veterans Bureau; died in Miami, Fla., February 8, aged 73, of coronary thrombosis and carcinoma of the lung.

Emery C. Pixley, Canisteo, N. Y.; University of Buffalo School of Medicine, 1891; at one time on the staff of the New York State Soldiers and Sailors' Hospital in Bath; died in St. James Mercy Hospital, Hornell, April 19, aged 82, of carcinoma.

John L. Powell, Aberdeen, Wash.; Medical College of Ohio, Cincinnati, 1891; at one time member of the board of regents of Washington State College, Pullman; died March 13, aged 86.

Arthur L. Pritchard, Nelsonville, Ohio; Medical College of Ohio, Cincinnati, 1886; member of the American Medical Association; past president of the Athens County Medical Society; served as a member of the city board of education; recently completed a third term as county coroner; died March 28, aged 80.

Joe M. Quinn, Bogalusa, La.; Kentucky School of Medicine, Louisville, 1892; died in New Orleans January 14, aged 78.

Morton C. Reeves, Palms, Calif.; University of Michigan Homeopathic Medical School, Ann Arbor, 1883; died January 23, aged 88.

Dabney Belvin Reinhart, Merrill, Wis.; Bellevue Hospital Medical College, New York, 1886; health officer; died March 13, aged 83, of myocarditis.

Isaac Reitzfeld ⊕ New York; University and Bellevue Hospital Medical College, New York, 1904; served in France during World War I; consulting orthopedist, Bronx Maternity and Woman's Hospital, New York, Long Beach Hospital, Long Beach, and Rockaway Beach (N. Y.) Hospital; director of orthopedics, St. Joseph Hospital, Far Rockaway, where he died April 8, aged 61, of uremia and hypertrophy of the prostate.

William Randolph Smith, Roselle Park, N. J.; College of Physicians and Surgeons, Baltimore, 1890; at one time president of the board of education in Little Falls; died in the New Jersey State Hospital, Marlboro, March 12, aged 83, of cerebral hemorrhage, arteriosclerotic cardiovascular disease and epithelioma of the nose.

Benjamin Franklin Vaughan, Bethany, Okla.; (licensed in Oklahoma under the Act of 1908); died in the University Hospital, Oklahoma City, February 21, aged 80, of pneumonia.

MERCHANT MARINE CASUALTY

Benjamin Andrew Price, Rigby, Idaho; Barnes Medical College, St. Louis, 1903; at one time on contract work with the Wyman Mining Company in San Javier, Sonora, Mexico, and the Vipont Silver Mining Company in Hazelton, where he was physician for the Union Pacific Railroad; served as Liberty County health officer and county physician while residing in Chester, Mont.; examiner for the Jefferson County Selective Service Board, Idaho National Guard, Civil Service, veterans insurance and many life insurance companies; health officer of Jefferson County, 1940-1941; in 1942 joined the Merchant Marine as a ship's medical officer aboard the S. S. *Delvalle,* which was attacked and sunk by an enemy submarine on April 12, 1942; aged 64; on May 23, 1944 posthumously awarded the Mariners Medal.

MEDICAL CARE OF VETERANS

To the Editor:—Your suggestion for a wholly independent investigation of the Veterans Bureau hospitalization seems to me sound and timely.

Regarding tuberculosis, the results might not lead promptly to a correction of the difficulty. The remedy may call for federal legislation not yet possible. If custom and regulations continue to make it too easy for patients to break treatment by leaves, passes, transfers, checking out against approval, and the like, its correction may have to wait on revised demands of veterans and their relatives and friends. This in turn has to wait on the progress of education, really health education.

Toward this educational end the American Legion and especially its Auxiliary and its Eight & Forty, aided by the voluntary tuberculosis associations, are taking definite steps. It is necessary to convince tuberculous veterans and their relatives that the treatment is medical and that it is important and that if they wish favorable results, such as are procured at similar hospitals under other auspices, it is really necessary for them to endorse and follow the prescriptions of their physicians.

In this effort all physicians and nurses and others truly desirous of aiding tuberculous veterans may assist. Then when the demand comes in volume from those whom it will most benefit it may be better understood and can be translated into favorable action by Congress and by the Veterans Bureau. This is not like the weather, because all together we can do something about it.

ARTHUR J. STRAWSON, Boston.
Executive Secretary, Massachusetts Tuberculosis League.

MARIHUANA PROBLEMS

To the Editor:—The editorial "Marihuana Problems" (THE JOURNAL, April 28, p. 1129) labels the Mayor La Guardia committee report "an unscientific, uncritical study" and, again, declares that it has "narrow and thoroughly unscientific foundation." The report in question came generally to the same conclusions that any other group of competent investigators might reach if they repeated the inquiry under the same conditions. Further, the New York report contained much new scientific information which is valuable. The editorial characterized the recent article in *War Medicine* (December 1944) as a "devastating refutation" of the La Guardia report, whereas this article simply described 35 cases of psychopathic or grossly maladjusted soldiers who used marihuana along with other manifestations of criminal behavior. The editorial primarily objected to the fact that the public may be led to mischievous results because the La Guardia report minimized the harmfulness of marihuana. A scientific study should be expected to report merely what it finds, avoid propaganda and let the public do what it will with the results. It is an old, familiar issue most sharply brought in focus by the frequent conflicts between temperance officials and those scientific workers who study the problems of alcoholism. The marihuana laws are adequate to suppress its use. (In fact they are so comprehensive as to have the indirect effect of obstructing legitimate researches with this unique drug.) Enforcement officials manifestly have a difficult job with grave responsibilities and it is unfortunate if some scientific publications might be thought to operate against their efforts. They should, however, have enough support for restraining criminal traffic in this drug, since all serious opinions, including the La Guardia report, have branded it an undoubted nuisance.

ROBERT P. WALTON, M.D., Charleston, S. C.
Professor of Pharmacology, Medical College of South Carolina.

SURVEY OF INTEREST IN PHARMACEUTICAL DEVELOPMENT

To the Editor:—In a recent survey to obtain indication of the probable postwar needs in academic and industrial organizations of those whose special interest lies in the development and use of drugs, inquiry was made of one hundred and thirty-five pharmaceutical and drug houses, seventy-seven medical schools and eighty-one foundations. Apparently all organizations plan to reemploy those on leave for service with the armed forces or on leave for other special work, although a comparatively small number will no doubt choose voluntarily to go elsewhere.

Many plans for expansion are being made and opportunities will be numerous for those qualified and willing to undertake teaching, research and administrative work. Expansion will be more extensive in industry than in academic centers, yet representatives of a number of schools anticipate enlargement of their institutions. Medical schools can provide full or part time teaching and research duties, fellowships, funds for which may be supplied by the university, foundation, drug manufacturer or other group, and merely space for study and research.

Pharmaceutical manufacturers can offer several types of work depending on the size of the organization: in the plant health department, which is responsible for the prevention and treatment of accidents and illness arising during employment; in the medical department, which is responsible for correspondence with physicians and inquirers, the accuracy of advertising claims, initiation of laboratory and clinical investigations; in the research department, in which are initiated studies of new drugs, and in the merchandising and promotion department. The men and women who will undertake work in this type of industry may have been trained as pharmacologists, bacteriologists, obstetricians, general practitioners, gynecologists, pediatricians, internists, pathologists and others. Of course, comparatively few of the latter will practice their special subjects; their work will depend on the department in which they are placed or to which they choose to apply their medical knowledge. Regardless of the specialty, however, these men have received basic medical training which, when coupled with a desire and aptitude for writing, research and executive or organizational activities, fits them for this type of work.

Foundations probably will provide fewer opportunities for full time work, but they will offer many fellowships.

Other places for specially trained medical men were not investigated, as the questionnaire was not intended to provide an exhaustive study. Otherwise, federal agencies such as the Food and Drug Administration, Federal Trade Commission and the National Institute of Health would have been included in the survey, as well as state and local health agencies, insurance companies, advertising agencies, radio broadcasting stations and other organizations.

Outstanding is the need for pharmacologists. Also in demand are individuals qualified to become toxicologists, medical writers, medical directors, bacteriologists, parasitologists, chemists and physiologists. Other specially trained personnel are also desired. The need for increased personnel in university centers is obvious. The need is equally obvious among pharmaceutical manufacturers, although the reasons for such scientific help are different. Of the three hundred institutions queried, about two hundred can probably supply well over three hundred additional positions, not including the vacancies created by men on leave for duty with the armed forces. This does not include fellowships, as the number which will be available is not possible to determine now.

AUSTIN SMITH, M.D., Chicago.
Secretary, Council on Pharmacy and Chemistry, A. M. A.

SANITARY DANGERS OF CROSS CONNECTIONS IN PLUMBING

To the Editor:—The editorial "Sanitary Dangers of Cross Connections in Plumbing" outlines a problem which is encountered in hospitals where the physical facilities are more than 15 years old. Few hospitals have an adequate water supply as judged by a study of dynamic pressures, so that sanitary plumbing is essential for safety. Administrators and hospital engineers have become calloused toward the problem, feeling that freedom from difficulty in the past indicates that sanitary plumbing is a luxury, too expensive to justify modernization of existing service. The profession has little knowledge of such matters and too often feels that 'sanitary plumbing' has esthetic implications but has little to do with good health. Local authorities are either apathetic or frustrated by the economic implications of correcting the situation. The American Medical Association can perform an outstanding service by sending trained experts into every hospital to inspect sterilizers, bath tubs, water closets, steam tables and laundry equipment as well as the general plumbing. An unbiased authoritative report to the trustees should stir most communities and even bureaucracies to corrective action.

CARL W. WALTER, M.D., Boston.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Liability of Corporate Employer for Physician-Employee's Negligence in Preemployment Physical Examination and Treatment.—Rannard and his wife instituted action for damages for malpractice against the Lockheed Aircraft Corporation and a physician in its employ. The first cause of action in the complaint alleged that the corporation employed the physician defendant in the conduct of its business; that Rannard applied to the corporation for employment and was found acceptable for employment subject to a required physical examination; that the corporation and the physician conducted the physical examination negligently, carelessly and unskilfully, and that as a direct result of such negligence the plaintiff sustained stated damages. The second cause of action incorporated the allegations of the first cause of action but elaborated on the employee relationship of the physician defendant and the corporation, alleging that the physician defendant was employed for the purpose of conducting physical examinations of applicants for employment and that the corporation in hiring and retaining the physician "negligently failed to select and employ a medical and surgical attendant physician and surgeon possessed of or capable of exercising that degree of care, skill, ability or learning possessed and exercised by medical and surgical attendants, physicians and surgeons practicing" in that locality. The third cause of action incorporated the allegations of the first cause but elaborated on the charge as to the negligent physical examination, alleging that Rannard was required to submit to such examination as a condition precedent to employment and was negligently advised by the defendants that it would be necessary for Rannard to submit to an operation to correct a purported "double hernia" and that Rannard did submit to such an operation performed by the physician, which operation was performed in a negligent, careless and unskilful manner. The final cause of action incorporated the substance of the first cause and incorporated by reference the allegations of the third cause with respect to the operation. In addition, the last cause alleged that after the operation the physician discontinued his employment with the corporation but continued to care for Rannard and that he did so negligently and that the corporation participated in and took an active part in that negligence and thereby ratified the act of the physician. There was a judgment on the pleadings in favor of the corporation, apparently on the ground that the details of the alleged negligence had not been set out. From an order of the trial court denying a new trial the plaintiffs appealed eventually to the Supreme Court of California.

The question here to be determined, said the Supreme Court, is whether the judgment on the pleadings in favor of the corporation was properly granted. In determining this question it is necessary to determine the sufficiency of the complaint on the same principle as though it had been attacked by general demurrer. In other words, only where there is an entire absence of some essential allegation may a motion for a judgment on the pleadings be properly granted. Under the applicable authorities, it is sufficient for a plaintiff to allege that an act was negligently done by the defendant and that it caused damage to the plaintiff. This rule has been applied in cases involving automobiles, in which it has been held sufficient to aver that the defendant negligently operated the vehicle without alleging how or in what respect it was done. This rule has also been applied in malpractice cases. *Dunn* v. *Duffey*, 194 Cal. 383, 228 P. 1029; *Ragin* v. *Zimmerman*, 206 Cal. 723, 276 P. 107; *McGehee* v. *Schiffman*, 4 Cal. App. 50, 87 P. 290. While, in malpractice cases, in addition to general allegations of negligence, the complaint may include a recital of certain related particulars, that fact does not deflect from the force of the general rule that it is sufficient in cases of this class to plead that the thing done was negligently done. The application of this rule is stated in *Abos* v. *Martyn*, 31 Cal. App. 2d 705, 88 P. 2d 797 as follows:

> It sufficiently appears from this complaint that what was done by this defendant was the administration of chiropractic treatments, which treatments, it was alleged, were negligently administered. Having alleged what was done and that the same was negligently done, the complaint was sufficient in the absence of a demurrer. While the defendant might have insisted upon greater certainty and particularity, he waived such defects by failure to interpose a special demurrer. As against a general demurrer, which is what an objection to the introduction of any evidence amounts to, the complaint is sufficient.

Tested by the requirements of the rule referred to, continued the court, the complaint in this case must be held sufficient. Negligence is expressly alleged with respect to three successive stages in medical services rendered Rannard: the diagnosis, the operation and the subsequent treatment. In relation to this premise of negligence, the complaint further alleges that "as a direct and proximate consequence and result" thereof various items of damage were sustained by the plaintiffs, thus satisfying the requirement of pleading "a causal connection between the act and the injury." 19 Cal. Jur. "Negligence," Sec. 101. The complaint here is couched in very general language but, as stated in *Dunn* v. *Duffey, supra:*

> All that is required of a plaintiff, as a matter of pleading, even as against a special demurrer, is that his complaint set forth the essential facts of the case with reasonable precision and with sufficient particularity to acquaint the defendant with the nature, source and extent of his cause of action.

The details of the specific act or omission on which the plaintiffs rely are matters of evidence which may be shown under the scope of the general negligence charge. The standard of pleading in negligence cases rests on consideration of fairness and convenience in view of the situation of the opposing parties, and the rule permitting the pleading of negligence in general terms as justified by the fact that the person charged with negligence may ordinarily be assumed to possess at least equal, if not superior, knowledge of the affair to that possessed by the patient.

The final question for the court's determination was with respect to the liability of the corporation for the alleged malpractice of the physician. The complaint, said the court, sets forth the relationship of principal and agent between the corporation and the physician, expressly charging not only that the physician was retained in the employ of the corporation in the conduct of and in furtherance of its business but also that the physician in rendering the specified medical treatment "at all times acted as the agent and employee" of the corporation and that the acts of the physician were done in the scope of and as a regular and routine part of his usual employment. This theory of pleading the joint responsibility of the corporation and the physician for the negligent acts of the physician was proper in view of the fact that the complaint alleged that Rannard was acceptable for employment "subject only to a physical examination" by the physician and that after submitting to such examination Rannard "as a condition precedent to the proposed employment" was required to undergo the operation in question. It is clear that the corporation employed the physician primarily to protect its own interests rather than the interests of the applicant and, under the doctrine of respondeat superior, it is liable for any injury proximately resulting from the malpractice of the physician. As is stated in 39 Corpus Juris, "Master & Servant," Sec. 356, pages 244 and 245:

> Where a physician is employed by the master but the relation of physician and patient does not exist between him and the servant, the rule of respondeat superior applies and the master may be liable for his negligence. In any event, in order to hold the employer liable for the negligent treatment of the employee, such negligence must be established, and the complaint must positively and directly allege the facts imposing liability.

A case illustrating the application of this rule is *Jones* v. *Tri-State Telephone & Telegraph Co.*, 118 Minn. 217, 136 N. W. 741, in which the plaintiff employee, who had been injured in the course of his employment, was required to submit to the taking of certain roentgenograms by a physician hired for such purpose by the employer. As a result of exposure to the roentgen rays the employee suffered injury. In sustaining the liability of the employer, the Minnesota court said:

> The relation of physician and patient did not exist between Dr. Roberts and plaintiff. The doctor was the servant of defendant. The case is the same, therefore, as if defendant's manager, or any other agent or employee, had inflicted the injury, and the rule of respondeat superior applies, rather than the law relative to the liability of a physician or surgeon to his patient, or to the liability of a master who employs a physician to treat his servant. There can be no doubt that defendant wanted the picture for its own purposes, probably as evidence in case plaintiff should bring suit against it to recover for the injury received in the accident.

The fact that here, in contrast to the situation in the Minnesota case, Rannard was a prospective rather than an actual employee would not deflect from the force of the general rule that the employer is liable for the injury sustained through the incompetence or want of skill of the physician acting as the employer's agent primarily in protecting the employer's interests. 35 Am. Jur. "Master & Servant," sec. 111, pages 539, 540. It is true that the corporation could not lawfully practice medicine, but this circumstance does not affect the application of the principle of agency. The claim that the subject of the agency—the practice of medicine—would constitute an ultra vires act by the corporation is of no avail as a premise to escape liability voluntarily assumed by the corporation in order to gain advantage or benefit for himself. *Hedlund* v. *Sutter Medical Service Co.*, 51 Cal. App. 2d 327, 124 P. 2d 878.

The court accordingly held that the pleadings in the present case sufficiently stated a cause of action against the corporation and accordingly reversed the judgment of the trial court denying the plaintiff's motion for a new trial.—*Rannard v. Lockheed Aircraft Corporation, 157 P. (2d) 1 (Calif., 1945).*

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and Examining Boards in Specialties were published in THE JOURNAL, May 26, page 308.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: Montgomery, June 26-28. Sec., Dr. B. F. Austin, 519 Dexter Ave., Montgomery 4.

ALASKA: Juneau, September. Sec., Dr. W. M. Whitehead, Box 561, Juneau.

ARIZONA: * Phoenix, July 5-6. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

ARKANSAS: * *Eclectic.* Little Rock, June 7. Sec., Dr. C. H. Young, 1415 Main St., Little Rock. *Medical.* Little Rock, June 7-8. Sec., Dr. D. L. Owens, 701 Main St., Little Rock.

CALIFORNIA: *Oral.* Los Angeles, Aug. 11. *Written.* San Francisco, July 9-12. Sec., Dr. Frederick N. Scatena, 1020 N St., Sacramento 14.

COLORADO: * Denver, July 3-7. Final date for filing application is June 18. Sec., Dr. J. B. Davis, 831 Republic Bldg., Denver.

CONNECTICUT: * *Homeopathic.* New Haven, July 10-11. Sec., Dr. J. H. Evans, 1488 Chapel St., New Haven. *Medical. Examination.* New Haven, July 10-11. *Endorsement.* New Haven, July 24. Sec. to the Board, Dr. Creighton Barker, 258 Church St., New Haven.

DELAWARE: *Examination.* Dover, July 10-12. *Reciprocity.* Dover, July 17. Sec., Medical Council of Delaware, Dr. J. S. McDaniel, 229 S. State St., Dover.

DISTRICT OF COLUMBIA: * *Reciprocity.* Washington, June 11. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington 1.

FLORIDA: * Jacksonville, June 25-26. Sec., Dr. Harold D. Van Schaick, 2736 S. W. Seventh Ave., Miami 36.

IDAHO: Boise, July 10. Dir., Bureau of Occupational Licenses, Miss Agnes Barnhart, 355 State Capitol Bldg., Boise.

ILLINOIS: Chicago, June 26-28. Superintendent of Registration, Department of Registration and Education, Mr. Philip Harman, Springfield.

INDIANA: Indianapolis, Aug. 28-30. Sec., Board of Medical Registration & Examination, Dr. W. C. Moore, 301 State House, Indianapolis 4.

KANSAS: Kansas City, June 26-27. Sec., Board of Medical Registration & Examination, Dr. J. F. Hassig, 905 N. Seventh St., Kansas City 10.

KENTUCKY: Louisville, June 18-20. Sec., State Board of Health, Dr. Philip E. Blackerby, 620 S. Third St., Louisville 2.

LOUISIANA: June 14-16. Sec., Dr. R. B. Harrison, 1507 Hibernia Bank Bldg., New Orleans 12.

MAINE: Augusta, July 10-11. Sec., Board of Registration of Medicine, Dr. A. P. Leighton, 192 State St., Portland.

MARYLAND: *Medical.* Baltimore, June 19-22. Sec., Dr. J. T. O'Mara, 1215 Cathedral St., Baltimore. *Homeopathic.* Baltimore, June 19-20. Sec., Dr. J. A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS: Boston, July 10-13. Sec., Board of Registration in Medicine, Dr. H. Q. Gallupe, 413-F. State House, Boston.

MICHIGAN: * Detroit, June 26-28. Sec., Board of Registration in Medicine, Dr. J. E. McIntyre, 100 W. Allegan St., Lansing 8.

MINNESOTA: * Minneapolis, June 19-21. Sec., Dr. J. F. DuBois, 230 Lowry Medical Arts Bldg., St. Paul 2.

MISSISSIPPI: Jackson, June 25-26. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson 113.

MISSOURI: St. Louis, June 7-9. Sec., State Board of Health, Miss Lucy Motley, State Capitol Bldg., Jefferson City.

MONTANA: Helena. Oct. 1-3. Sec., Dr. O. G. Klein, First Nat'l. Bank Bldg., Helena.

NEBRASKA: * Omaha, June 19-21. Final date for filing application is June 4. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, 1009 State Capitol Bldg., Lincoln 9.

NEW JERSEY: Trenton, June 19-20. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

NORTH DAKOTA: Grand Forks, July 3. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

OHIO: *Endorsement.* Columbus, July. *Examination.* Columbus, June 18-21. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

OKLAHOMA: * Oklahoma City, June 14-16. Sec., Dr. J. D. Osborn, Jr., Frederick.

SOUTH CAROLINA: Columbia, June 25-27. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

SOUTH DAKOTA: * Pierre, July 17-18. Sec., Medical Licensure, State Board of Health, Dr. Gilbert Cottam, State Capitol, Pierre.

TEXAS: Galveston, June 4-6. Houston, July 17-19. Sec., Dr. T. J. Crowe, 918-20 Texas Bank Bldg., Dallas 2.

VERMONT: Burlington, June. Sec., Dr. F. J. Lawliss, Richford.

VIRGINIA: * Richmond, June 20-23. Sec., Dr. J. W. Preston, 30½ Franklin Rd., Roanoke.

WASHINGTON: * Seattle, July 16-18. Sec., Department of Licenses, Miss Nell Adams, Olympia.

WEST VIRGINIA: Charleston, July 5-7. Commissioner, Public Health Council, Dr. John E. Offner, State Capitol, Charleston 5.

WISCONSIN: * Milwaukee, June 26-28. Sec., Dr. C. A. Dawson, Tremont Bldg., River Falls.

WYOMING: Cheyenne, June 4-5. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

COLORADO: Denver, June 6-7. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver.

CONNECTICUT: June 9. Address State Board of Healing Arts, 250 Church St., New Haven 10.

MINNESOTA: Minneapolis, June 5-6. Sec., Dr. J. C. McKinley, 126 Millard Hall, University of Minnesota, Minneapolis 14.

OREGON: Portland, July 7. Sec., Mr. C. D. Byrne, University of Oregon, Eugene.

SOUTH DAKOTA: Yankton, June 19. Sec., Dr. G. M. Evans, Yankton.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Heart Journal, St. Louis

29:143-280 (Feb.) 1945

Clinical and Theoretical Considerations of Involvement of Left Side of Heart with Echinococcal Cysts: Review of Literature, with Report of 5 New Cases, Including 1 Observed by Authors. J. H. Peters, L. Dexter and S. Weiss.—p. 143.
Heart Disease in the South: I. Statistical Study of 1,045 Cardiac Deaths. Alice B. Holoubek.—p. 168.
*Incidence of Heart Disease and Rheumatic Fever in School Children in Three Climatically Different California Communities. J. J. Sampson, P. T. Hahman, W. L. Halverson and Margery C. Shearer.—p. 178.
*Coronary Occlusion After Fever Therapy for Sulfonamide Resistant Gonorrheal Urethritis. A. M. Harvey and F. T. Billings.—p. 205.
Periodic Changes in Form of P Waves in Partial Heart Block. D. Scherf.—p. 213.
Negative Displacement of RS-T Segment in Electrocardiogram and Its Relationships to Positive Displacement: Experimental Study. C. C. Wolferth, S. Bellet, Mary M. Livezey and F. D. Murphy.—p. 220.
Treatment of Orthostatic Hypotension, with Particular Reference to Use of Desoxycorticosterone. R. Gregory.—p. 246.

Heart Disease and Rheumatic Fever.—The school populations of three California communities with different climates were surveyed for the incidence of heart disease, rheumatic fever, functional heart murmurs and hypertension. Rheumatic fever and rheumatic heart disease occur in the warm dry climate of Redlands in a degree comparable to cities with mild temperate climates, such as Cincinnati and San Francisco. Susanville, a mountain community with average humidity and precipitation but with wide extremes of winter and summer temperatures, presented a high incidence of rheumatic fever and rheumatic heart disease, comparable to the incidence in the northeastern United States or Great Britain. Eureka, with a uniformly cool climate and high precipitation, presented an unusually high incidence of rheumatic disease, especially of valvulitis. Certain statistical relations seem to exist between rheumatic disease and age, sex, race and housing. Questionable relations exist to diet and to a history of scarlet fever. Definite relation of functional murmurs to any physical, symptomatic or environmental influences, such as age, shape of chest or nutritional state, was not found.

Coronary Occlusion After Fever Therapy.—Harvey and Billings used fever therapy in the treatment of 85 young men with chronic gonococcic urethritis resistant to sulfonamide therapy. Three patients aged 24, 19 and 25 respectively developed electrocardiographic changes typical of occlusion of a coronary artery after fever therapy. In 1 case there were never any symptoms referable to the heart, and in the other 2 they were relatively mild and the illness was never serious. Electrocardiograms in each case showed progressive changes similar to those which occur with occlusion of the anterior descending branch of the left coronary artery. In 2 cases definite T wave changes were still present eight and ten weeks after the onset. In the third case a record made fifteen weeks after the therapeutic hyperpyrexia revealed normal T waves. Subsequently, in 15 cases, records were made routinely before and for three days after therapeutic hyperpyrexia. In 2 of these the electrocardiograms showed a coronary type of ST segment and T wave change within twenty-four hours, which persisted for several days but then reverted to normal. Neither patient had complaints referable to the cardiovascular system. In several others a transient cardiac arrhythmia was observed in addition to minor changes in the ST segments and T waves.

Isoimmunization to Factor P by Blood Transfusion. A. S. Wiener and L. J. Unger.—p. 616.

American Journal of Medical Sciences, Philadelphia

209:281-420 (March) 1945

Clinical Observations on Outbreak of Jaundice Following Yellow Fever Vaccination. J. M. Hayman and W. A. Read.—p. 281.
Anaerobic Septicemia: Report of 6 Cases with Clinical, Bacteriologic and Pathologic Studies. J. D. Reid, G. E. Snider, E. C. Toone and J. S. Howe.—p. 296.
Coincidence of Allergic Disease, Unexplained Fatigue, and Lymphadenopathy: Possible Diagnostic Confusion with Infectious Mononucleosis. T. G. Randolph and R. A. Hettig.—p. 306.
Use of Bromsalizol in Lengthening Effect of Sympathetic Nerve Block. F. C. Lee, D. I. Macht and R. Z. Pierpont.—p. 314.
Spermatogenic Activity of Various Steroids. G. Masson.—p. 324.
Meigs Syndrome in Case of Multilocular Pseudomucinous Cystadenoma of Ovary. J. Millett and J. Shell.—p. 327.
Relation Between Cell Pack (Hematocrit) Volumes and Lymphocyte Counts. F. T. Jung, O. E. Hepler and M. S. Maynard.—p. 336.
Pernicious Anemia and Carcinoma of Stomach Autopsy Studies Concerning Their Interrelationship. H. S. Kaplan and L. G. Rigler.—p 339.
Coronary Insufficiency Revealed by Ectopic Nodal and Ventricular Beats in Presence of Left Bundle Branch Block. E. Simonson, N. Enzer and J. S. Goodman.—p. 349.
Large Interauricular Septal Defect, with Particular Reference to Diagnosis and Longevity: Report of 2 New Cases. J. B. Burrett and P. D. White.—p. 355.
Developments in Arthritis. R. Pemberton.—p. 364.
*Poliomyelitis in Pregnancy. M. J. Fox and L. Sennett.—p. 382.

Poliomyelitis in Pregnancy.—During the epidemic of poliomyelitis in 1943, 6 women with poliomyelitis were admitted to the Milwaukee Isolation Hospital. The fact that 4 were pregnant seems to indicate that pregnancy increases susceptibility to poliomyelitis. Increased susceptibility to poliomyelitis in pregnancy may be due to the change in ovarian secretion at that time, although pituitary dysfunction and fetal hormones upsetting the mother's balance may also be suspected. In the 4 cases of poliomyelitis complicating pregnancy at the Milwaukee Isolation Hospital, delivery of 2 normal children and examination of 1 fetus in a dead mother confirmed the opinion that poliomyelitis in the mother has not affected the newborn child, nor does it prevent normal spontaneous delivery.

Engineering Technic Applied to Restaurant Sanitation. W. S. Johnson.—p. 257.
*Sanitary Aspects of Control of 1943-1944 Epidemic of Dengue Fever in Honolulu. W. E. Gilbertson.—p. 261.

Sanitary Aspect of Control of Dengue.—Gilbertson says that dengue again made its appearance in epidemic form in Honolulu, Territory of Hawaii, in 1943, after an absence of over thirty years. The supposition that the disease was imported from the Southwest Pacific is based on the knowledge of the cases of 2 airline pilots who were hospitalized with

dengue in Honolulu after arrival from Suva, Fiji Islands, where an epidemic of dengue had been reported. The Honolulu dengue epidemic is believed to be one of few outbreaks of such proportions to be suppressed largely by mosquito control. Sanitary controls used were (1) citywide premise to premise inspections to reduce incidence of the vectors, Aedes aegypti (Linneas) and Aedes albopictus (Skuse), (2) comprehensive exterior-interior spraying to eliminate foci of dengue infection and (3) public education to urge householders to prevent mosquito breeding on their premises. Aedes breeding indexes were satisfactorily reduced by these efforts, while simultaneous spray work destroyed adult mosquitoes in zones of high dengue incidence. Comprehensive spray treatment of the epidemic foci was followed by a sharp reduction in cases. A total of 1,498 civilian cases occurred from July 1943 through June 1944, less than 0.7 per cent of the population contracting the disease.

Chemotherapy of Syphilis. J. E. Moore.—p. 185.
Effect of Sodium Hydroxide on Biologic Falsely Positive and Anticomplementary Serologic Reactions in Syphilis. H. Brown, J. A. Kolmer and Elsa R. Lynch.—p. 200.
Relative Activity of Partially Purified Penicillin and of Crystalline Penicillin G on Treponema Pallidum. W. B. Dunham and G. Rake.—p. 214.

Syphilitic Meningitis Treated with Penicillin.—Nelson and Duncan report the effects of intramuscular injections of sodium penicillin on acute syphilitic meningitis in 10 patients treated at the Johns Hopkins Hospital. The total amount of penicillin administered varied from 600,000 to 4,000,000 units; the duration of treatment varied from seven and one-half to eleven days. The treatment schedule advised for acute syphilitic meningitis is a total dosage of 2,000,000 to 3,000,000 Oxford units of penicillin administered every three to four hours day and night for from eight to sixteen days. Although penicillin does not appear in the cerebrospinal fluid even after frequent intramuscular administration, the drug is effective in acute syphilitic meningitis when given by the intramuscular route. None of the 10 patients treated have so far developed evidence of clinical relapse, though 1 has shown relapse in the spinal fluid.

Etiology and Immunology of Granuloma Inguinale.—Anderson and her associates report experiments in which a micro-organism having morphologic identity with the Donovan body and specific antigenic relationship to patients with granuloma inguinale has been isolated and serially cultivated in the yolk of developing chick embryos. The Donovan micro-organism has been isolated and cultivated from 3 cases of granuloma inguinale. From the cultured strain a bacterial antigen has been prepared that elicits an apparently specific skin reaction in patients with the disease. A so-called capsular substance, precipitable from infected embryonic yolk, fixes complement and gives a positive precipitation test in combination with patient's serum and also stimulates a skin reaction in patients with granuloma inguinale. Successful cultivation of the Donovan micro-organism depends on the isolation of uncontaminated pieces of human tissue infected with Donovan bodies. The Donovan micro-organism survives in extirpated human tissue as long as ninety-six hours at 37 C. This permits the isolation of uncontaminated bits of recently removed infected tissue on the surface of a solid medium that would indicate contaminants by the gross appearance of colonies. Ordinary blood agar plates or slants were satisfactory in this initial step of isolation. With the elimination of contaminated fragments of tissue, Donovan bodies in a pure state in human tissue can be introduced into the yolk of developing chick embryos 5 to 6 days old, where they find a favorable invironment for growth. Although multiplication proceeds slowly, a small inoculum will initiate a pure culture.

American Review of Tuberculosis, New York

51:205-294 (March) 1945

*Pulmonary Alveolar Adenomatosis in Man: Is This the Same Disease as Jaagsiekte in Sheep? D. A. Wood and P. A. Pierson.—p. 205.

Types of Tubercle Bacilli in Birds and Mammals: Their Incidence, Isolation and Identification. A. M. S. Stadnichenko, H. C. Sweany and J. M. Kloeck.—p. 276.

Pulmonary Alveolar Adenomatosis.—A woman aged 57 had presented pulmonary symptoms for two years. Dyspnea with an initial dry cough gradually becoming productive constituted a prominent feature of the disease. Thin walled tension cavities developed in the right lower lobe. One of the cavities was opened surgically, sulfanilamide powder was instilled into the wound and the wound was tightly closed. The lesions in the lobectomy specimen resembled those of a noncaseating disseminated miliary tuberculosis. The most prominent microscopic feature was the multicentricity of hyperplastic columnar epithelial cells lining the alveolar walls, showing all degrees of proliferation from simple lining to papillary and cystadenomatous arrangements. Adenomatosis was confined to the right lower lobe for over a year. Foci were found in the other lobes post mortem. An adenoacanthoma of the uterine cervix was discovered three months prior to the patient's death. It had resulted in numerous distant metastases, most of which were below the diaphragm. Wood and Pierson are of the opinion that the uterine cancer developed independently of the pulmonary lesion.

Hyperthyroidism and Thiouracil.—Palmer reports observations on 50 unselected patients treated with thiouracil. Twenty-two of these had received the drug for a minimum of three months, but only 6 had received it for as long as nine months. The only criterion for treatment was that the basal metabolic rate had to exceed +30 per cent. Five of the patients had had one or more partial thyroidectomies. Twenty-two patients had received previous treatment with iodine, the results being unsatisfactory. The dosage schedule, which was arrived at without determination of blood concentration, was as follows: 0.1 Gm. of thiouracil every three hours for three days, 0.1 Gm. every four hours for three to six days and then 0.5 or 0.4 Gm. daily until clinical improvement is sustained. It is probable that 0.6 Gm. of thiouracil is the optimal maximum daily dose. With each dose of thiouracil 10 grains (0.65 Gm.) of sodium bicarbonate was given. All the patients treated during the past five months have received 100 mg. daily of ascorbic acid and also liver extract. Capsules of multivitamin concentrates were given two to three times a day. Every patient now receives thyroxin or desiccated thyroid. The thiouracil treatment failed in none of the patients, but some responded more satisfactorily than others. In general the higher the initial basal metabolic rate, the more dramatic was the response. It is believed that vitamins, sedation and rest enhance the efficiency

of thiouracil but have little intrinsic curative properties. There is a trend toward a normal endocrine balance on thiouracil therapy alone, but the restoration is brought about more completely and with less unpleasant side reactions when thyroid substance is given in combination with thiouracil. The patient coming to operation is treated in the same manner as one with simple colloid goiter, with the exception that measures are taken to control the greater vascularity encountered in a thyroid treated with thiouracil.

Thiouracil in Preoperative Management of Hyperthyroidism.—Thiouracil has been used at the Lahey Clinic in the preoperative management of 64 patients with hyperthyroidism. Fifty of the patients had primary hyperthyroidism or exophthalmic goiter and 14 patients had adenomatous goiter with hyperthyroidism. The duration of hyperthyroidism ranged from three months to fifteen years. The initial basal metabolic rate varied from +21 per cent to +98 per cent, the average rate being +51 per cent. Fifteen patients with adenomatous goiter were classified as thyrocardiac, having either heart failure or auricular fibrillation without heart failure. When thiouracil is used, maximum improvement must be striven for; patients should not be sent to operation until a normal or nearly normal basal metabolic rate is recorded. Unfavorable results in 2 cases of partial preoperative control with thiouracil has induced the authors to continue daily administration of 0.6 Gm. of thiouracil until the basal metabolic rate is practically normal and hyperthyroid symptoms have subsided. Approximately one day of treatment with thiouracil is required for each per cent of elevation in the basal rate. When the first patients receiving thiouracil underwent thyroidectomy the gland was found to be soft and friable, and bleeding was so extensive that there was difficulty in carrying out the usual surgical technic. The difficulty was overcome when Lugol's solution was administered with thiouracil. Thiouracil is given until the basal metabolic rate approaches +20 per cent, when iodine is started. It is continued for three weeks preoperatively, the thiouracil being discontinued one week before operation. This method produced a satisfactory state of involution, as determined at operation and by microscopic examination. Thiouracil is valuable in the preoperative management of hyperthyroidism.

Intercapillary Glomerulosclerosis.—Goodof observes that a history of diabetes mellitus was recorded in 214 of 10,000 consecutive necropsies performed at Washington University School of Medicine from 1910 to 1942. Microscopic sections of the kidneys and pancreas were studied. In all cases showing evidence of intercapillary glomerulosclerosis or of hyalinization of the islands of Langerhans, additional sections were prepared and stained with Heidenhain's aniline blue. Several series of controls were selected. One of these included 214 patients without diabetes mellitus. This group was chosen so that the ages corresponded with those of the test series. Another control series was composed of 100 consecutive nondiabetic patients in whom the kidneys showed arteriolar disease. To study the part played by age in the development of intercapillary glomerulosclerosis, 50 nondiabetic patients over 70 years of age were examined, and a similar number from 5 to 20 years of age. On the basis of these investigations it appears that intercapillary glomerulosclerosis occurs in 44 per cent of diabetic patients. Women are more likely to show the lesion than men, in a ratio of 10:7. It is more prevalent in patients whose diabetes is of long duration, and who are in older age groups. There is no association with insulin treatment. Thirty per cent of nondiabetic persons over 70 years of age have mild lesions of intercapillary glomerulosclerosis. None are present in a group of nondiabetic patients between 5 and 20 years of age. Mild lesions are present in 10 per cent of the population as a whole. Advanced lesions are present only in patients with diabetes mellitus. Clinically, the diagnosis of intercapillary glomerulosclerosis is justified in a patient who has had mild or moderately severe diabetes mellitus for a considerable period, usually over six years, who excretes albumin in the urine without evidence of other renal disease to account for the albuminuria.

Metrazol and Electric Shock in Psychoses.—The Ziskinds present a comparison of treated and untreated patients with affective psychoses who were seen in private practice between 1938 and 1943. Of 88 patients treated the first 58 received metrazol and the other 30 were given electric shock therapy. The untreated control group included 109 patients, of whom 43 refused convulsive therapy, 50 had symptoms which were too mild to warrant this treatment and 16 had physical disease which contraindicated the method. The follow-up results were full remission in 90 per cent of the treated patients and in 75 per cent of the untreated patients. In the untreated patients there were nine deaths from suicide and four deaths from exhaustion, as compared with one death from suicide in the series of treated patients. Two patients with heart disease died during treatment. The incidence of ultimate full remission for patients with the longest period of follow-up observation (from June 1938 to June 1941) was about the same (88 and 86 per cent) for treated and for untreated patients respectively, provided the deaths were omitted from each series. New attacks occurred with almost equal frequency in the control and in the treated series. Thus the tendency to recurrence is apparently not influenced by treatment. Subconvulsive doses, incomplete therapy and old age are unfavorable factors. Subconvulsive reactions should be avoided. The benefits of convulsive therapy are to be gaged by the reduced period of illness and the decreased number of deaths. The treatment in itself is not responsible for any greater incidence of recovery than that which occurs spontaneously if the patient is shielded from death by suicide or exhaustion.

Erotomania as Expression of Epileptiform Discharge.—Erotomania as the initial manifestation of a cortical epileptiform discharge has not previously been described. Erickson's patient, a woman, began to manifest nymphomania in paroxysms of short duration at the age of 43. For two years she presented no symptoms other than the nymphomania. The significance of this symptom was evident only when the same sensory experience was followed by jacksonian seizures and finally by progressive hemiplegia. Examination finally revealed the presence of a neoplasm causing excitation of the topical projection of the genital structures in the right paracentral lobule. A year after operative removal of the neoplasm the nymphomania had disappeared.

Experimental Nonparalytic Poliomyelitis.—A series of 37 monkeys inoculated intracerebrally with material from throat swabs of poliomyelitic patients were examined histopathologically to make certain that nonparalytic poliomyelitis was not

missed as well as to confirm the clinical diagnosis of poliomyelitis in the paralytic monkeys. Ten of the 37 monkeys suffered attacks of poliomyelitis. Of these, 9 were paralyzed and 1 had a nonparalytic infection. The pathologic findings in all cases were typical of poliomyelitis. The occurrence of 1 nonparalytic infection in a total of 10 monkeys inoculated intracerebrally is to be compared with a similar frequency of nonparalytic infections in monkeys inoculated intranasally with human and chimpanzee stools (human stools, 45 paralytic and 5 nonparalytic; chimpanzee stools, 43 paralytic and 7 nonparalytic). Sixteen of the 23 negative animals examined histologically presented scattered perivascular infiltrations in the pia mater, which were interpreted as nonspecific reactions to the inoculation. Cord passage to 2 normal rhesus monkeys in each of 7 of these cases gave a negative result. The range of pathologic involvement in nonparalytic infections, as in paralytic cases, was found to be wide.

Poliomyelitis Virus in Oropharynx.—Howe and his collaborators state that poliomyelitis virus was recovered from half of 14 patients hospitalized in New Haven in 1943. In 20 cases studied in 1943 in New Haven and of 16 in Chicago the virus was recovered in 10, or 28 per cent This figure gives little idea of the factors actually involved In the 20 New Haven cases virus was isolated from 8 (40 per cent), while in the 16 cases of the Chicago series virus was found in only 2, or 12 per cent. This disparity is explained by the fact that in no instance was virus isolated after the third day of the disease. The apparently unfavorable result in the Chicago series was occasioned by the fact that two thirds of the swabs were obtained between the fourth and the ninth day of illness, whereas two thirds of the New Haven material was collected by the third day.

Meningitis.—Silverthorne reviews 166 cases of influenzal meningitis and 271 cases of meningococcic infection (all bacteriologically proved) which were observed at the Hospital for Sick Children in Toronto between 1919 and 1944 The use of sulfonamides has been the most important method of treatment shortening the course and reducing the fatality Influenzal meningitis has been sporadic in its occurrence. Meningococcic infections were sporadic until 1939, but from 1940 to 1943 there was an increase in the incidence of cases of this infection. Bacteriologically, 70 of the 71 spinal fluid strains examined from patients with influenzal meningitis have been type B. Meningococcic infections during a sporadic occurrence of the disease have usually been caused by strains of type II. During an increase in the incidence of this infection in 1941 and 1942 there was a decided increase in the occurrence of group I strains. Most patients with influenzal meningitis followed after recovery have been normal mentally and physically. All patients with meningococcic infection treated with sulfonamides or with serum and sulfonamides have been normal on discharge from the hospital.

Weather and Ascorbic Acid in the Common Cold.—Brown and his associates present an analysis of the spread of the common cold through a group of 1,600 girls of college age, as affected by the weather, use of cigarets and relative susceptibility to the common cold, of the season to season changes in

physiologic fitness and of the effect, on duration of the common cold, of early recognition and the use of ascorbic acid in massive dosage. Sharp increases in the number of new colds per day occurred during periods of falling temperature accompanied by heavy rain. The increases began and were most steadily sustained in the girls with a total of four or more colds for the year. The smokers had a tendency to precede the nonsmokers. The rises in the incidence of colds precipitated by the weather tended to begin twenty-four to forty-eight hours after the beginning of the weather change and to persist for twenty-four to forty-eight hours after its cessation. Deterioration in average physiologic fitness occurred with the progress of the year in a small fraction, which was partially balanced by a smaller group showing improvement. The smokers appeared to be slightly less fit than the nonsmokers. Nose involvement predominated in the fall colds and throat involvement in the winter colds. A total of 298 patients with colds were studied for the ascorbic acid appraisal; 119 of these were controls who were given placebos of citric acid. Approximately 60 per cent of the colds with throat involvement appeared to respond only to the basic management given both the control and the ascorbic acid groups (restriction of activity, precaution against chilling and increased fluid intake) with a spontaneous checking of further development. The colds with nose involvement were equally responsive if recognized and submitted to care within seven hours of onset. For those not submitted to care until eight to twenty-eight hours after onset, the percentage of spontaneous checking was 59 ± 5 for those given 1 Gm. of ascorbic acid at examination and again twenty-four hours later and 21 ± 4 for those given citric acid.

Violacein, an Antibiotic Pigment of Chromobacterium Violaceum.—According to Lichstein and Van De Sand the interest in Chromobacterium violaceum has been increased by the isolation of this germ from fatal human infections. The pigmentation surrounding the "anthrax-like" lesions of the skin and the relative absence of contaminating organisms in the lesions suggested the possibility that some metabolic product of this organism might possess an inhibitory action against certain forms of bacteria, particularly those found abundantly in the normal flora of the skin. The authors obtained 4 strains of Chr. violaceum, 3 of which were isolated from fatal human infections and were called the Shahan, Soule and Schattenberg strains and a fourth which was an old saprophytic laboratory strain. Those from pathologic sources produced a rich violet pigment, whereas the saprophytic strain exhibited little or no pigmentation during growth. Violacein was extracted from cultures of the Shahan strain in order to test antibiotic activity against micro-organisms. The pigment exhibited a considerable inhibitory effect on the growth of gram positive bacteria with the exception of Clostridium welchi and had little effect on the proliferation of gram negative bacteria save the meningococcus, which was highly susceptible. Of the molds tested, only Blastomyces dermatiditis was greatly susceptible to the action of the pigment. The activity of violacein is influenced only slightly by the number of bacteria in the test inoculum and is influenced strongly by the presence of serum.

Periarteritis Nodosa and Hypersensitivity.—Wilson and Alexander analyzed 300 consecutive cases of periarteritis nodosa and found many instances of associated atopy and atopic-like disorders. Particular attention was paid to bronchial asthma, of which there were 54 cases, an incidence of 18 per cent. When differential blood counts were available, all but 3 of 47 cases of asthma showed a hypereosinophilia ranging from 11 to 84 per cent, with an average of 53.5 per cent. This is in contrast to 151 cases without asthma in which there were but 9 instances of hypereosinophilia and the average eosinophil count was 2.5 per cent. Periarteritis nodosa appears to be the only evident manifestation which links together all types of human hypersensitivity with the exception of contact dermatitis. This fact points again to the role of the blood vessels in hypersensitive states.

Demonstration of Anti-Rh Agglutinins by Rapid Slide Test.—Diamond and Abelson describe a slide test for the detection of anti-Rh agglutinins. Approximately 0.2 cc. of fresh, oxalated, Rh negative, Rh_2 and Rh_1 group O whole bloods or washed cells are placed on an ordinary slide. With each of these is mixed 0.1 cc. of the serum to be tested. The mixture is gently rotated or repeatedly tilted. The reaction is accelerated when the slide is warmed to 37 C. Reading of the test is facilitated by holding the slide on a piece of ground glass placed over an ordinary electric light. When the serum is from a sensitized individual, plainly visible agglutination appears in one, and usually in both, of the Rh positive bloods usually within a minute and certainly within three minutes. The Rh negative blood serves as a control to eliminate errors through mistaking fibrin shreds, rouleau formation or nonspecific agglutination for actual Rh agglutination. In contrast to the incubation test, which fails to show the presence of anti-Rh agglutinins in over 50 per cent of cases, chiefly because of the presence of inhibitor substances, this slide test has demonstrated agglutinins in the serums of 79 of 80 women who have delivered infants with proved erythroblastosis fetalis and in 9 persons who had been sensitized by transfusions of Rh positive blood cells. In addition to demonstrating Rh sensitization in a higher percentage of cases than does any other single test, it more nearly pictures what is likely to occur in vivo when a relatively large amount of agglutinogen is ordinarily exposed to a smaller amount of agglutinin. Another advantage is that it permits the use of testing serums heretofore considered of no value.

Effect of Penicillin on Plague in Guinea Pigs.—Witlin and Wilbar prepared a pure culture of Pasteurella pestis organisms from a rat infected with plague. Guinea pigs weighing from 250 to 300 Gm. were used as experimental animals. Penicillin was administered prior to, simultaneously with and subsequent to the inoculation with P. pestis organisms. Penicillin appeared to be of no benefit in combating bubonic plague in guinea pigs. In vitro a concentration of 100,000 units of penicillin in Dunham's peptone solution was required to kill an inoculum of 2,500,000 P. pestis organisms when incubated at 29 C. for six days.

Urinary Lithiasis in Army General Hospital.—Harrison and his associates present observations on 100 consecutive patients with urinary calculi who were admitted to an army general hospital in the Southwest Pacific. It is their belief that climate is an important factor in the pathogenesis of urolithiasis, particularly in an army stationed in the tropics, owing to the great loss of water by perspiration, evaporation and respiration. Sustained dehydration results in the excretion of highly concentrated urine saturated with oxalate and phosphate salts, predisposing to urinary infection as well. Owing to such conditions, attacks of crystalluria accompanied by showers of red cells and transitory renal colic have occurred and, when continued without correction, have resulted in the formation of calculi. Malnutrition and debilitating tropical diseases such as malaria and dysentery disturb the water, mineral and acid base balance. Of the first 100 patients treated for calculous disease, 76 had served in the tropics for four to eighteen months and all of these had lost weight varying from 10 to 30 pounds (4.5 to 14 Kg.). Sixty-eight of the men were in the third decade, 25 were in the fourth decade and 7 were in the fifth decade. The management of these patients has been directed toward accurate localization of calculi, the treatment of infection and provision for drainage when obstruction is present by cystoscopic manipulation, ureteral catheterization and open operation where indicated. The soldier who has passed a calculus or who has been relieved by operative removal should be instructed as to the importance of a high fluid intake to prevent recurrence. Adequate salt consumption is important in the body's conservation of water in the tropics. Dietary measures should be instituted as prophylaxis against stone formation where practicable. Thirty-five patients were relieved of calculi as a result of cystoscopic manipulation; of 31 who required no operative intervention, 15 passed calculi spontaneously; 37 open operations were performed on the remaining 34 patients.

Prevention of Recurrence in Peptic Ulcer.—Quigley advises that after the acute stage of peptic ulcer has passed the ulcer patient gradually should have added to his diet roughage and food which is not easily digested. A function not used is a function lost. Whole grain flour should be used as soon as possible after the acute stage of the disease. The

so-called enriched flour is still lacking in many vital elements and should be forbidden the ulcer patient for life. Sugar furnishes calories without vitamins or minerals. It is a slow poison for the ulcer patient. Honey contains all necessary minerals (many trace minerals) and can thus be used freely for sweetening. The principal reason for the use of milk is that it is the best source of calcium. There is no need to neutralize excess acid with alkalis. Milk will relieve the pain and furnish other valuable elements. Orange juice should be used in the amount of 10 to 12 ounces a day. It is also alkaline in its effect and furnishes vitamin C and trace minerals. Biscuits, bread, muffins, waffles and pancakes made of whole grain flour can be used at a relatively early date after the acute episode. Any fruit or vegetable that can be served raw should be eaten raw. Fresh meat, rare when possible, should be eaten daily in amounts of from 3 to 6 ounces. No salt meat except occasional ham or breakfast bacon is allowed. Eggs, cheese, butter and cottage cheese may be used daily, but one or two meals a week should contain one of the sea foods. All cake, cookies, pastries and other sugar and white flour mixtures are forbidden. Sedatives and alkalis are of only temporary value, and the need for them rapidly diminishes when the patient is put on proper treatment.

Intraperitoneal Absorption of Sulfonamides.—Pearce and his associates describe experiments which revealed that sulfathiazole introduced into the peritoneal cavity of normal dogs in the form of microcrystals was more rapidly absorbed than was crystalline sulfathiazole when compared on the basis of concentrations of drug in the plasma. Microcrystalline sulfathiazole injected into the peritoneum as a suspension gave higher concentrations of drug in blood plasma than did comparable amounts administered by insufflation, although the response to the former was not uniform High and sustained concentrations of sulfathiazole in plasma can be obtained by intraperitoneal injection of a suspension of microcrystals Simultaneously collected samples of blood from the portal vein and the heart contained practically identical concentrations of sulfonamide drugs sixty to three hundred and sixty minutes after intraperitoneal administration either as crystals or as microcrystals

Staphylococcus Toxoid in Staphylococcic Infections.—The study by Jern and her associates comprised a group of 200 cases of staphylococcic infections The majority were cases of recurrent furunculosis, most of which had proved resistant to other forms of therapy. The rest consisted of cases of axillary abscesses, cases of acute multiple furuncles and carbuncles A majority of the patients were treated with Lederle peptic digest toxoid alone. Some received a combined treatment with Lederle toxoid and autogenous vaccine and a few were treated with vaccine alone. The treatment of 93 patients with recurrent furunculosis and axillary abscesses with Lederle's pepsin digest toxoid resulted in a complete recovery of only 38 per cent. In the remaining 62 per cent recurrences developed within one year after the end of the treatment. Of 40 patients with recurrent furunculosis and axillary abscesses treated with Connaught toxoid 31, or 78 per cent, recovered. The 9 others had recurrences within the year The authors found that the antihemolysin test is not a strict measure of immunity, for there are exceptional cases in which there is a rise in titer and recurrences, and others in which no rise occurs and yet recovery seems to ensue. There may be some other immune factor which does not run strictly parallel with the antihemolysin titer which is of major importance but cannot be measured. The authors conclude that Staphylococcus toxoid made from toxigenic strains is able by means of repeated injections to increase the antihemolysin titer of the blood and to lessen significantly the incidence of recurrence of furuncles and carbuncles

Heterophoria and Neurosis.—Beccle and Kitching review observations on 57 cases of heterophoria in flying personnel. They find that heterophoria and neurosis frequently coexist and that in 50 of the 57 cases heterophoria was a symptom of hysterical and part of a generalized psychologic illness, which is the primary and major disorder. References to the literature indicate that this conclusion applies also to civilian cases. It is customary to give orthoptic, i. e. local, treatment in heterophoria, but in the treatment of neurotic symptoms local treatment alone is not enough. It should be preceded by a psychiatric examination Orthoptic treatment alone may cause the heterophoria to disappear. It will not cure the neurosis or render the patient less vulnerable to a recurrence. On the other hand it may confirm a hypochondriacal eye consciousness and render ultimate psychologic treatment much more difficult. Whether it should be employed or not, and what other measures are desirable, should be decided by collaboration between the ophthalmologist and the psychiatrist. The ultimate prognosis seems to depend more on the emotional stability of the patient than on the degree of ocular muscle imbalance

Choice of Sulfonamide in Ophthalmia Neonatorum.—On the basis of 333 cases of ophthalmia neonatorum treated with a standard dose of five different sulfonamides Sorsby and Hoffa conclude that the least tolerated drug is sulfanilamide and that sulfapyridine is less well tolerated than sulfamezathine, sulfathiazole or sulfadiazine. In their efficacy against the infection, as distinct from their tolerance by the babies, these five sulfonamides are not strikingly different. From 30 to 40 per cent of the cases in this series showed clinical cure within three days. Over 80 per cent were cured after eight days. Gonococcic ophthalmia neonatorum responds more readily than other varieties of ophthalmia. Cases showing inclusion bodies respond satisfactorily. Initial severity does not affect the course unfavorably. Many severe cases clear rapidly. Irrespective of the causal organism some 15 per cent of cases show a sluggish or poor response.

*Cysticercosis (Tenia Solium) Further Ten Years' Clinical Study, Covering 284 Cases H. B. F. Dixon and W. H Hargreaves —p 107.
Action of Intravenous Digoxin in Man J. McMichael and E P. Sharpey Schafer.—p. 123.
Effects of Trauma, Direct and Indirect, on Heart H. Barber —p 137.

Cysticercosis (Tenia Solium): 284 Cases.—Dixon and Hargreaves have followed up all patients with cysticercosis who are still living and in addition they have collected a further 185 cases, bringing the total to 284. Cysticercosis in man results from accidental infection with the larval form of Tenia solium. This is brought about either by the ingestion of food or drink contaminated by human feces containing ova or by autoinfection in the host of a tapeworm. Seventy-seven patients in 284 gave a history of tapeworm. Of the series under consideration 274 were infected in India and 269 of them were soldiers and ex-soldiers. A history of "fits" varying from transient bouts of localized paresthesias and minor attacks possibly suggestive of petit mal to severe major epileptiform convulsions after residence in India must bring to mind the possibility of cysticercosis. Epileptiform attacks of jacksonsian type are well recognized, but minor symptoms are extremely common. Cysticerci disseminated throughout the brain may produce any variety of focal symptoms, motor, sensory or mental. Commonly elicited histories are those of transient monoplegias, paresthesias, localized anesthesia, visual and aural symptoms, aphasia and amnesia. A search for nodules by inspection and palpation of the whole body is the first step toward diagnosis. There was a history of transient nodules under the skin in 165 patients. The total number of cases in which the diagnosis was made radiographically came to 212. In a suspected case of cysticercosis radiographic search of the whole body is indicated. Too much importance has been attached to eosinophilia. It was found in only 10 per cent of the cases reviewed here The average period intervening between the time of arrival in India and the first cerebral symptoms was seven years. The time of appearance of nodules also varies greatly. The mortality from cysticercosis in this series has been only 8 per cent, with improvement in patients whose outlook for years appeared hopeless.

Permanent Recovery from Cancer of the Breast Report of 150 Cases with Duration of Life from Fifteen to Thirty Years A Hintze. —p 672.

Osteomyelitis with Eosinophil Reaction. — Schairer describes a peculiar bone lesion in 3 of his own cases and in 12 cases listed in world literature. The lesion is designated as osteomyelitis with eosinophil reaction or as eosinophilic granuloma of bone. It presents a localized destructive process of bone-plates in the calvarium, ribs or scapula The clinical picture is that of a swelling above the involved bones. It develops in several weeks and is associated with more or less severe pain on palpation. Spontaneous pain was infrequent. There may be a slight rise of temperature. Microscopic examination revealed a characteristic picture of soft masses which replace the bone. There was granulation tissue rich in cells with large reticulum cells or fibroblasts, numerous mature eosinophilic leukocytes and giant cells of osteoclastic type. Necrosis in the granulation tissue or microabscesses, as well as deposits of hemosiderin, were demonstrated in some of the cases Eosinophilia of the blood and of the bone marrow was observed in some of the cases, and eosinophilia of a regional lymph node was found in 1. The prognosis is favorable. Recovery resulted in all cases. Treatment consists in the removal of the soft granulations. The cause of the disease is not known and bacteria could not be demonstrated Trauma may have been a causative factor in some of the cases

Book Notices

Atlas of the Blood in Children. By Kenneth D. Blackfan, M.D., and Louis K. Diamond, M.D., Assistant Professor of Pediatrics, Harvard Medical School, Boston. Cloth. Price, $12. Pp. 320, with illustrations by C. Merrill Leister, M.D., Associate Pediatrician, St. Luke's Hospital, Bethlehem, Pennsylvania. New York: Commonwealth Fund; London: Oxford University Press, 1944.

This atlas fills a much needed want in the library of most physicians. Besides the seventy brilliantly executed colored illustrations of blood cells in normal and pathologic states in infancy and childhood there is a brief but adequate description and discussion of various diseases affecting the blood forming organs at that period of life. The illustrations were done by Dr. Leister and reflect not only artistic ability but a keen perception of the finer morphologic detail of blood cells. The organization of the atlas is practical and expedient. The illustrations are so arranged as to aid the inexperienced to identify rapidly the predominant type of cell he finds in the questionable blood smear. The purpose of the atlas is not to replace experienced hematologic investigation of the patient but rather to provide orientation in this difficult field so that the need of such investigation will be apparent. Those interested primarily in hematology might take exception to the use of the term megaloblast to indicate an early member of the normal red cell series, but there are two sides to this question and in an overall estimation of the atlas this is an insignificant criticism. While the atlas will serve the pediatrician and the student especially, the illustrations depict morphologic detail of cells found in adult blood and should be useful to the general practitioner as well. The clinical descriptions are concise but complete. Essential information is not sacrificed because of brevity, and the material reflects the rich clinical background in hematology of Dr. Diamond and the late Dr. Blackfan. A well selected bibliography follows the descriptive material so that the reader may be well guided if he seeks further detail about any of the conditions discussed in the text. The book can be confidently recommended not only as an atlas but also as a concise and authoritative textbook of diseases affecting the blood forming organs of infants and children. Every medical and hospital library will want a copy of this unique atlas. The private sale among pediatricians, general practitioners and students will more than justify the cost of subsidizing this excellent presentation by the Commonwealth Fund. An atlas of this type could not have been made available at such a moderate price without that financial support. This bargain, then, which the Commonwealth Fund has provided, is a "must" for the practitioner's library.

Massage and Remedial Exercises in Medical and Surgical Conditions. By Noël M. Tidy, Sister-in-Charge of the Red Cross Massage Clinic, High Wycombe. Sixth edition. Cloth. Price, $6. Pp. 480, with 190 illustrations. Baltimore: William Wood & Company, 1944.

This edition presents material that is interesting, well organized and compact. It deals with problems that confront the physical therapist at various times. War injuries are not treated as fully in other textbooks. The divisions for each case such as etiology, pathologic changes, symptoms, after-effects and treatment give a vivid picture of the case. The physical treatment is defined and, if one is interested in that phase mainly, the book will prove to be a valuable source of information. Under treatment the subdivisions on precautions, prevention and remedial measures, treatment of specialized cases and treatment of severe cases are helpful. The illustrations are good and the explanations of the photographs are clear. The illustrations selected go well with the material and can readily make the reader understand what the author desires to explain. They also reflect the effect of movement and activity.

Pep, Pills and Politics: An Odyssey of Two States. By Arthur W. Hopkins, M.D. Cloth. Price, $2.50. Pp. 239, with 23 illustrations. Brattleboro, Vermont: Vermont Printing Company, 1944.

To add to the many works of reminiscences of the growth and development of physicians comes now this simple account of a practice in New England. The record contains in it much of amusement, much that is sentimental, a great deal that is of the warp and woof of general practice. Those who have had similar experiences will give it a most sympathetic reading.

Shoulder Lesions. By H. F. Moseley, M.A., D.M., M.Ch., Assistant Surgeon, Royal Victoria Hospital, Montreal. Cloth. Price, $4.50. Pp. 181, with 71 illustrations. Springfield, Ill.: Charles C Thomas, 1945.

This book presents a concise account of present day knowledge of shoulder lesions. The author has avoided detailed accounts of controversial subjects. He acknowledges that much of his information and enthusiasm were derived from Codman's masterpiece "The Shoulder." He has carried on the work where Codman left off. He discusses the use of procaine in diagnosis and therapy; the accumulation of knowledge on the morbid anatomy of simple and recurrent dislocations, the early diagnosis and treatment of complete ruptures of the "rotator cuff" of the shoulder, the recognition of lesions of the long tendon of the biceps, the application of Lewis and Kellgren's work on referred pain from muscles and fascias to the subject of fibrositis and the painful shoulder, the understanding of the cervical disk and scalenus syndromes, the advances in the diagnostic and therapeutic value of x-rays and the establishment of the position of rest and motion in shoulder disorders. Each chapter was written as a unit. Calcified deposits and the bicipital syndromes form separate groups of cases with definite pathologic changes, whereas the groups included under periarthritis are those with a similar symptom complex but with varying underlying causes. There is a chapter on neurologic aspects of shoulder pain by McNaughton and another on x-ray diagnosis and treatment by Bouchard and Peirce. There has been an attempt to stimulate interest in the subject by focusing attention to the arm-trunk mechanism rather than on the glenohumeral or shoulder joint. Some of the most interesting chapters cover the mechanism and examination of the shoulder, ruptures of the rotator cuff, subluxation and dislocations, calcified deposits in the rotator cuff, bicipital syndromes, periarthritis and specific injuries. Operative procedures are described and illustrated. There is a section on reeducation of shoulder function. One of the features of the book is a group of 30 representative case reports that are interesting and instructive. Unfortunately the recent work of Inman, Saunders and Abbott could not be included because Moseley's book was already in print.

Essentials of Allergy. By Leo H. Criep, M.D., Assistant Professor of Medicine, School of Medicine, University of Pittsburgh, Pittsburgh, Pa. With a foreword by Robert A. Cooke, M.D. Cloth. Price, $5. Pp. 381, with 43 illustrations. Philadelphia, London & Montreal: J. B. Lippincott Company, 1945.

This book faithfully and successfully carries out the purpose announced in its preface. It is specifically designed for the undergraduate medical student and for the general practitioner. With this limitation in mind, this is an excellently written, well organized book, covering in a concise way a wealth of information on allergy. Immunology is not neglected. In the first twenty-six pages Criep gives briefly an excellent summary of the subject. The author skilfully saves space by avoiding repetition. An example is furnished in the chapter on nasal allergy. Under "treatment" the author refers to chapter v, on treatment of allergy. The forty-two black and white illustrations and the one color plate are quite adequate for undergraduate teaching purposes. They show the excellent discrimination and teaching experience of the author. Case reports at the end of many chapters are well chosen to accentuate the clinical subjects discussed. To summarize, this is one of the best books on allergy written specifically for the undergraduate student and the practicing physician.

A Textbook on Pathology of Labor, the Puerperium and the Newborn. By Charles O. McCormick, A.B., M.D., F.A.C.S., Clinical Professor of Obstetrics, Indiana University School of Medicine, Indianapolis, Ind. Cloth. Price, $7.50. Pp. 399, with 191 illustrations. St. Louis: C. V. Mosby Company, 1944.

In spite of the title, since only 27 of the 399 pages are devoted to the newborn, the book is almost exclusively limited to the pathology of labor and the puerperium. In the section on the pathology of labor the author includes abnormal labor, obstetric injuries, postpartum hemorrhage and obstetric operations. In the section dealing with the pathology of the puerperium are included puerperal infection, late postpartum hemorrhage, anomalies and diseases of the breast and other complications of the puerperium. The book is written in outline or symposium form and the references are inserted throughout the text instead

of at the end of each chapter. The author uses the terms pituitrin and ergotrate instead of the nonproprietary names posterior pituitary injection and ergonovine. Throughout the book are indications of a conservative attitude. However, like most obstetricians, McCormick favors cesarean section for placenta previa patients who have a rigid, closed or only slightly dilated cervix. The author's personal choice of forceps is the Tarnier with axis traction or Irving with axis traction, but most obstetricians seldom resort to axis traction. At the end of the book is a list of fifty aphorisms which are very useful. The book is abundantly and well illustrated and can be highly recommended to all physicians who want a separate volume devoted to the pathology of labor and the puerperium. This book does not, of course, attempt to supplant the standard textbooks of obstetrics, which contain much more material.

Home-Built Electric Dehydrator. Prepared by Bureau of Human Nutrition and Home Economics, Agricultural Research Administration, U. S. Department of Agriculture. AWI-76. Paper. Pp. 12, with illustrations. Washington, D. C.: Supt. of Doc., Government Printing Office, 1944.

This pamphlet gives detailed directions and layout specifications for the construction of a home made food dehydrator. Step by step directions are provided for assembling the drier with its eight wire mesh trays and thermostatically controlled electric heating unit capable of maintaining a temperature of 150 F. Any handy home mechanic should have no difficulty preparing the equipment, although such materials as a ¼ horsepower motor, thermostat, wiring and heating elements may prove difficult to obtain today. Careful directions are given for preparing fruits and vegetables for the drier, with lists of the foods best suited to this method of preservation. It is recommended that light colored fruits be sulfured first to prevent darkening and that vegetables be steamed first to inactivate the enzymes. Tests are given to determine when the necessary degree of dryness has been attained. The booklet provides adequate directions to guide the home maker in the fabricating of a dehydrating unit and its profitable use subsequently.

The Specificity of Serological Reactions. By Karl Landsteiner, M.D. With a chapter on Molecular Structure and Intermolecular Forces by Linus Pauling. Revised edition. Cloth. Price, $5. Pp. 310, with illustrations. Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1945.

The textual revision was completed before the author's death in June 1943. Much new material has been included. In his preface the author mentions with regret that the most recent European literature, other than British, could not be considered because it was not available. The original plan of the book has been maintained. The first chapters deal with natural antigens and antibodies; then artificial conjugated antigens and the serologic reactivity of simple chemical compounds (including experiments on "drug allergy") are considered; chapters 6 and 7 are devoted to the chemistry of specific nonprotein cell substances and to the consideration of antigen-antibody reactions from a physiochemical approach. The chapter by Linus Pauling on molecular structure and intermolecular forces concludes the text. Every paragraph in this classic book reveals the firm, comprehensive grasp of serologic problems by a great investigator.

The Etiology, Diagnosis, and Treatment of Amebiasis. By Charles Franklin Craig, M.D., M.A., F.A.C.S. Cloth. Price, $4.50. Pp. 332, with 45 illustrations. Baltimore: Williams & Wilkins Company, 1944.

This is the second monograph published by the author on the same subject. It is up to date and covers the subject thoroughly. About 10 per cent of the population of the United States have an infection with the Endameba histolytica parasite. At present a large number of our troops are serving in regions where amebiasis is common and many will come back infected and add a serious factor to the problem. Hence it is vital that all physicians become familiar with the diagnosis and treatment of this treacherous infection. The author believes that there are no "healthy carriers." The parasite invades the tissue of its host and produces lesions. These lesions may be microscopic and may be accompanied by symptoms, but many of them may develop acute trouble later on. The chapters on the etiology, pathology and symptomatology are complete, clear and concise. The treatment is given in full detail for both acute and chronic cases and includes all the complications.

State Board Questions and Answers for Nurses: Essay and Objective Types. Compiled from Actual Examination Questions Given Throughout the Country by State Examining Boards. Twenty-third edition. Cloth. Price, $3.50. Pp. 1,159, with 5 illustrations. Philadelphia, London & Montreal: J. B. Lippincott Company, 1945.

The twenty-third edition of this useful volume brings the work up to date with the addition of certain new material covering visual devices for fact testing. This involves various simple line drawings about which questions are asked, especially in the field of anatomy, physiology, surgical nursing, obstetrics and gynecology. The book contains questions which have been asked in state board examinations throughout the country covering all fields of nursing education in a well organized manner. Each question is followed by the correct answer. The answers have been reviewed by an editorial panel consisting of competent authorities in this field. There are essay type questions as well as objective forms. The brief essay "To the Student Preparing for the State Examination" contains numerous useful suggestions and principles in writing board examinations. It is necessary to sound a note of warning in connection with the use of books of this kind. There is always the danger of an undue emphasis on examinations and the substitution of question and answer study for the sounder methods based on textbooks, journals and reference volumes. Memorizing of answers may replace a sound understanding of the subject matter. The Editorial Panel is aware of this danger and advises the student that the "goal should be a thorough knowledge rather than a passing grade." The proper use of the book should be to supplement the textbook review of each subject by going through the questions in this book. "Do not study the answer with the question, but ask yourself the question and attempt to answer it. Check your answer with that in the book and find out which is the better answer."

Clinical Lectures on the Gallbladder and Bile Ducts. By Samuel Weiss, M.D., F.A.C.P., Clinical Professor of Gastroenterology, N. Y. Polyclinic Medical School and Hospital. Cloth. Price, $5.50. Pp. 504, with 125 illustrations. Chicago: Year Book Publishers, Inc., 1944.

In his preface to the book Dr. Weiss states that these lectures as presented are to be regarded as a guide in the diagnosis and treatment of the patient. This is indeed the key to the book. Starting with the basic formulas of medicine the reader is led through anatomy, physiology and thence to history taking and the physical examination of the patient. Then after a section on radiology comes an evaluation of the discussion of clinical material on diseases of the gallbladder. Treatment of the subject is complete, clear and comprehensive as to etiology, pathology, diagnosis and therapy. Stress is laid on the fact that therapy must be individualized and that frequently other organs are involved in gallbladder disease. Thus mention is made of arthritis, the pancreas and so on. The book is as adequate a treatise as any available, and it is to be recommended as an addition to the best list of references on the subject.

A Shorter History of Science. By Sir William Cecil Dampier (formerly Whetham), Sc.D., F.R.S. Cloth. Price, $2. Pp. 189, with 23 illustrations. New York: Macmillan Company; Cambridge: University Press, 1944.

The place of medicine in the whole picture of science becomes apparent in this easily readable contribution from Cambridge. The approach is from the point of view both of the subject and of the pioneer who gave to that subject a new trend. By far the majority of the work is concerned with subjects ancillary to medicine, but there are good notes regarding the development of anatomy, physiology and biology. The concluding chapters dealing with the new physics and chemistry and the stellar universe are an indication of our present trend in science.

Eighth Annual Report of the Empire Rheumatism Council (to Organise Research Throughout the British Empire into the Causes, and Means of Treatment, of Rheumatic Disease), 1944. President: H. R. H. The Duke of Gloucester, K.G. Paper. Pp. 12. London, [n. d.].

For eight years the Empire Rheumatism Council, which was organized to foster research throughout the British Empire into the causes and means of treatment of rheumatic disease, has issued an annual report of its accomplishments. During the past year there has again been an increase in the reserve fund of the council. Clinical research, of course, has been hampered by the war, but its resumption soon under favorable conditions should be greatly assisted by this organization.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

BLOOD TRANSFUSION IN RH SENSITIVITY

To the Editor:—*Is Rh incompatibility ruled out if, for transfusions, the recipient's blood is cross matched with the donor's—cells against serum and serum against cells—and no agglutination is observed? If, for example, a woman who is Rh negative but who has been sensitized to Rh positive blood by a transfusion of Rh positive blood or by pregnancy with an Rh positive fetus is to receive a transfusion, would cross matching show up the incompatibility by agglutination even though both recipient and donor were of the same blood type but the donor was Rh positive? If no agglutination occurs in cross matching why should there be a transfusion reaction?*

Alexander Soloska, M.D., Salisbury, Pa.

ANSWER.—It has been found that many Rh negative patients though strongly sensitized to the Rh factor, as proved by the occurrence of severe hemolytic reactions following transfusions of Rh positive blood, nevertheless do not have detectable anti-Rh agglutinins in their plasma (Wiener, A. S.: Hemolytic Reactions Following Transfusions of Blood of the Homologous Group: II. Further Observations on the Role of Property Rh, Particularly in Cases Without Demonstrable Isoantibodies, *Arch. Path.* **32**:227 [Aug.] 1941). In a few cases this has been explained by the performance of the tests for anti-Rh agglutinins too soon after the transfusion which caused the hemolytic reaction, at which time the patient is in a negative phase as the result of the absorption of the Rh agglutinins from the plasma by the hemolyzed Rh positive cells. Frequently the phenomenon can be explained by the presence of a special sort of Rh antibody (blocking antibodies) in the patient's plasma (Wiener, A. S.: A New Test [Blocking Test] for Rh Sensitization, *Proc. Soc. Exper. Biol. & Med.* **76**:173 [June] 1944). The blocking antibodies have the capacity of combining specifically with Rh positive blood cells, but without producing a visible reaction. To detect blocking antibodies, Wiener recommends the following technic: A drop of a 2 per cent. suspension of Rh positive red cells and a drop of the patient's serum are mixed in a small test tube and allowed to react in a water bath at 38 C. for thirty to sixty minutes. Then a drop of a suitable dilution of an active anti-Rh serum is added, and after an additional period of incubation for thirty to sixty minutes the reactions are read. If blocking antibodies are present, no agglutination will occur or the clumping will be definitely weakened. Obviously, then, the routine cross matching tests are inadequate to detect all instances of Rh incompatibility, so if the presence of Rh sensitization is suspected it is safest to use an Rh negative donor, unless one precedes the transfusion by a biologic test (Wiener, A. S.: Blood Groups and Transfusion, ed. 3, Springfield, Ill., Charles C Thomas, 1943, p. 71).

CONTRACEPTIVE METHODS

To the Editor:—*Is there a vaginal jelly that can be used as a contraceptive agent with reasonable safety? The diaphragm in this particular instance has resulted in another pregnancy. The patient is not yet 20 years old and has had four babies.*

M.D., Iowa.

ANSWER.—Contraceptive jellies which have been accepted by the Council on Pharmacy and Chemistry of the American Medical Association have a spermicidal time of under thirty minutes as tested by the Brown and Gamble method and may be used alone as contraceptive agents with reasonable safety. Indeed, they are usually sold with an applicator appropriate for this type of use. However, the protection afforded by this technic is definitely less than that provided by the diaphragm and jelly together.

ADMINISTRATION OF INTRAVENOUS SOLUTIONS

To the Editor:—*Will raising a bottle of intravenous solution two to three feet when it is already four feet above heart level affect the rate of flow in the vein? Are there any venous reflexes which would impede the rate of flow of the solution into the vein in a normal individual?*

Eli Kamellia, M.D., Fresno, Calif.

ANSWER.—The rate at which fluid flows from a bottle of intravenous solution into the vein depends on the viscosity of the fluid, the resistance offered by the tubing and needle and the relation between venous pressure and the height of the bottle. Hence, other things remaining constant, raising the bottle will increase the rate of flow in proportion to the amount by which the hydrostatic pressure in the infusion system exceeds the venous pressure.

Irritation of a vein, as by venipuncture or by the injection of irritating solutions, may in some instances produce spasm of the vein, but this usually disappears after a short time. Under ordinary conditions such spasm is not often observed, and a slow rate of flow into a vein in a normal person is usually due to mechanical blockage which can almost always be overcome by readjusting the position of the needle.

DIAPER WHITE

To the Editor:—*Is the preparation Diaper White a safe one to use in cleaning infants' diapers?*

Charles A. Weymuller, M.D., Brooklyn.

ANSWER.—There is reason to believe that Diaper White essentially is a mixture of alkaline water softeners, about one half the product being sodium carbonate (soda ash) and the remaining half representing smaller quantities of trisodium phosphate, pyrophosphate and soap. Freedom from irritants on diapers after the use of this substance almost entirely rests on the degree of rinsing. If diapers are washed by hand there is some risk of skin irritation on contact surfaces. This product is similar to other substances used in connection with laundering or other types of cleaning.

PERSISTENCE OF CUTANEOUS LESIONS IN SYPHILIS

To the Editor:—*A man aged 33 consulted me about three and a half months ago for the treatment of syphilis. Three years ago a primary lesion developed which was treated with sulfarsphenamine: he received 0.4 Gm. intramuscularly weekly for twelve doses and then monthly for the remainder of a three year period. During this time lesions appeared recurrently on the glans and on the scrotum. When I first examined him, all observations were normal except for annular lesions on the scrotum and a few papules on the glans, undoubtedly syphilitic. His weight was 220 pounds (99.8 Kg.). Wassermann and Kahn reactions of the blood were positive for syphilis. The spinal fluid contained 15 white blood cells per cubic millimeter; there was a positive reaction for globulin, a gold curve of 5554320000 and a total protein count of 44 mg. per hundred cubic centimeters; the Wassermann reaction of the spinal fluid was positive for syphilis. I started him on 0.06 Gm. of mapharsen twice weekly and 0.2 Gm. of bismuth subsalicylate once a week. The skin lesions showed decided improvement in ten days. After nineteen injections of mapharsen, however, there was a slight flare-up of the lesions on the scrotum. The patient was immediately hospitalized and given 2,400,000 units of penicillin, 40,000 units intramuscularly every three hours, and concurrently received 0.04 Gm. of mapharsen daily for a total of eight doses. During the last three days of this treatment he was given two baths to produce hyperpyrexia, as I was unable to schedule him for electropyrexia. Following dismissal from the hospital I started him on bismuth alone, but on his second visit to the office I again noticed an exacerbation of the scrotal lesions. What plan of treatment would you suggest for this patient?*

Harry L. Douglas, M.D., Kansas City, Mo.

ANSWER.—The treatment given to this patient when the chancre was first recognized might account for the persistence of the mucocutaneous relapses and accordingly is subject to criticism. Sulfarsphenamine given at weekly intervals for twelve doses followed by monthly injections for three years is a poor system of treatment for early syphilis, first because of the inefficiency of sulfarsphenamine, secondary because the intervals between injections were much too long and thirdly because a heavy metal such as bismuth was not also employed. Recurrences of lesions of the mucous membrane are frequently seen in patients when arsenicals are received at irregular intervals or when the time between injections is too long or if heavy metals are omitted, as in this case. It must be acknowledged, however, that occasionally a patient is encountered who will develop a mucocutaneous relapse in spite of intensive treatment An alternative consideration is that not all annular lesions on the genitalia are due to syphilis, because lichen planus also produces annular lesions. In view of the inability to prevent the recurrences of the lesions with penicillin, nineteen injections of oxophenarsine hydrochloride (mapharsen) and an equal number of injections of bismuth subsalicylate should be given and, in view of the reaction of the spinal fluid, a course of fever therapy, preferably malaria therapy. Four months after the fever course, or sooner if the recurrent lesions reappear, the use of arsphenamine in doses of 0.3 to 0.5 Gm. at five day intervals for ten injections and a soluble mercurial, such as mercuric succinimide in ⅙ grain (11 mg.) doses six times a week for three weeks should be tried. Occasionally the use of arsphenamine given simultaneously with daily intramuscular injections of a mercurial will prevent recurrences of a lesion of this type when the newer arsenicals have failed to do so.

VENOUS THROMBOSIS AND PULMONARY EMBOLISM

FURTHER EXPERIENCE WITH THROMBECTOMY AND FEMORAL VEIN INTERRUPTION

ARTHUR W. ALLEN, M.D.
ROBERT R. LINTON, M.D.
AND
GORDON A. DONALDSON, M.D.
BOSTON

In previous communications from the staff of the Massachusetts General Hospital we have indicated that we are confronted with a serious problem concerning venous thrombosis with resulting pulmonary embolism.

Hampton and Castleman [1] have shown that infarcts to the lungs are easily interpreted by roentgenographic studies. Many of the postoperative pulmonary sequelae, previously attributed to other causes, are embolic in origin. Castleman,[2] from autopsy studies, has found the source of pulmonary embolus in our clinic to be from the deep veins of the legs in approximately 95 per cent of the cases.

Miller and Rogers [3] in earlier studies recognized the importance of this syndrome in our clinic. Data collected by Davis [4] prior to 1925 showed that 3 patients in each thousand subjected to major surgical procedures succumbed to pulmonary embolism. Methods to prevent venous stasis by posture, combined with early passive and active exercise, reduced the incidence of fatal embolus to approximately 1 in 800 surgical patients.[5] Even this improvement did not eliminate the terrific morbidity with which we were confronted, since all conservative methods of treatment of thrombophlebitis in our clinic included a prolonged period of bed rest and hospitalization.

It will be obvious to all that venous thrombosis is more common in certain clinics and in certain geographic locations than in others. In the deep South, clinics treating a similar group of patients to ours will have fewer instances of thrombosis and consequently fewer deaths from pulmonary embolism. Also it is obvious that the average severity of the process in warmer climates is milder and response to conservative treatment better. In those regions where respiratory tract infections approximate those seen in New England during the summer months, thrombosis and embolism in severity and incidence correspond more closely to our experience during the warm season (table 1).

"Bland thrombosis," Homans,[6] or "phlebothrombosis," Ochsner and De Bakey,[7] produces a symptomless, afebrile condition in our section of the country with resulting unexpected fatal pulmonary embolism. We are impressed, however, by all gradations from completely reactionless bland thrombosis to typical phlegmasia alba dolens. Many patients with phlebothrombosis will progress to the painful tender, swollen extremity stage with fever, leukocytosis and high sedimentation rate seen in typical thrombophlebitis. Often this change in character of the process is further complicated by the fever and leukocytosis accompanying pulmonary infarct. Although we recognize the comparative safety as regards massive pulmonary embolism in true thrombophlebitis, we feel that the course of this disease can be altered by radical treatment if recognized in the first days of the process. We do not believe that femoral vein interruption has any place in the treatment of true thrombophlebitis after the seventh day of the disease unless infarcts have occurred. We do see cases with phlebothrombosis and repeated infarcts that can be satisfactorily treated by vein interruption weeks after the onset of the process. It is obvious to us that, the earlier the diagnosis of phlebothrombosis or thrombophlebitis with immediate bilateral femoral vein interruption, the shorter the period of disability. If one delays operation until repeated infarcts have occurred or until swelling of the leg has existed for a week or more, then the convalescence will be prolonged and the outcome doubtful. This is due to the time required for the dissolution of the embolic process in the lungs as well as for the subsidence of swelling in the extremities. Both early and late edema of the legs are greatly influenced by the extent and duration of the thrombosis prior to thrombectomy and vein interruption.

The age of the patient is of utmost importance in the consideration of the danger of fatal embolism in thromboembolic disease. Clinics treating a high percentage of elderly patients with serious pathologic processes will encounter a larger ratio of thrombosis and embolism. Welch and Faxon showed the importance of the age factor in our clinic.[5] The older the patient, the greater likelihood of fatal embolus complicating illness or surgery. A personal communication from these men now serving in a general army hospital in a foreign zone brings the fact that in 10,000 wounded and sick soldiers treated there were only 7 instances of

thrombophlebitis. Two factors are responsible for this difference in their own experience, the previous physical fitness and youth of the patients being primary, while a warm climate doubtless must be taken into consideration. We have become so impressed with the increased danger from fatal pulmonary embolus in the aged that we have actually carried out prophylactic femoral vein interruptions on 34 patients since Jan. 1, 1943. We

believe that future reports from our clinic may give a very decided increase in the ratio of this preventive measure. Veal [8] has advocated concomitant femoral vein interruption in low thigh amputations. This is a precaution we have used a few times and one we shall use more often in the future.

This method of treatment may seem radical in the younger patient (table 2). Actually the process rarely produces fatal embolus in patients under 40 years of age. Since death occasionally occurs in this group, it is justifiable for this reason alone. In addition to this we know that sublethal infarcts and prolonged hospitalization can be avoided in this age group by the early recognition and radical treatment of phlebothrombosis and thrombophlebitis. The late sequelae of postphlebitic phlegmon and ulcer is reduced to a minimum if thrombectomy and femoral vein interruption with its early ambulation are carried out.

In the cardiac group we are asked to do femoral vein interruption if infarct occurs or if there are any signs of thrombosis in the leg veins. Recently we have had a few requests for this operation as a prophylactic

procedure. It is well known that many of the pulmonary infarcts in cardiac patients come from the heart itself. We have shown, however, that a fair proportion of these emboli come from the legs in this group of patients.[9] Femoral vein interruption has not been responsible for a single death in our clinic to date. For these reasons the cardiologists feel that this operation is indicated in these patients on slight provocation It allows them to discount the possibility of a fatal embolus from the leg veins.

A small group of patients with fracture of the hip region requiring operative procedures have been subjected to prophylactic femoral vein interruption. This has been brought about by the frequency of fatal embolus in these aged patients, particularly those with intertrochanteric fractures. Elderly men requiring prostatectomy are beginning to be considered in the same light as are those who are to undergo serious operations for malignant disease. It is hoped that we may be able to work out better criteria for prophylactic vein interruption. At the moment we are not urging this practice. If it could be standardized we could prevent approximately five deaths a year in our clinic from massive embolus that occur in the aged group of patients who give no warning of phlebothrombosis This may be illustrated by the following case report:

Patient M., aged 74, was referred to us with extensive cancer of the stomach. Aside from considerable weight loss due to anorexia, he was in fair condition After proper

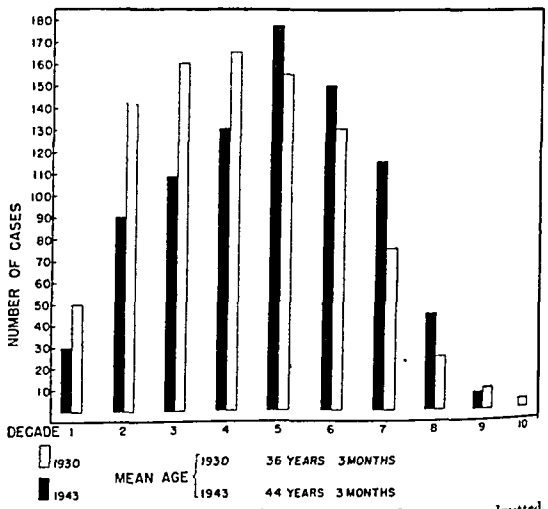

Fig 1.—Age in decades and the mean age of patients admitted to the surgical services of the Massachusetts General Hospital for a corresponding three month period in 1930 and 1943 Note the greater number of patients admitted in 1943 between the ages of 40 and 80 years Many of these required major surgery for malignant disease Both of these factors, age and malignancy, increase the incidence of thromboembolic disease

preparation he was subjected to total gastrectomy by the abdominal approach. He did well and was taking a liberal bland diet by his fourteenth postoperative day. He complained at this time of malaise and lack of any interest in food as well as slight discomfort in the epigastrium. He was afebrile, and physical examination revealed only a slight amount of tenderness in the well healed operative region. There was a small amount of edema of his ankles, present before operation and attributed to nutritional deficiency. There was no evidence of tenderness in the calves or popliteal regions or over the course of the deep leg veins, and no dilatation of the superficial veins. He had no pain in his chest, no cough and no leg symptoms. The change in his condition was explained on the basis of overfeeding and reaction about the operative region. He improved during the next forty-eight hours and was taking food well. On his nineteenth postoperative day, while returning from the bathroom, he collapsed in the corridor and died within five minutes. Autopsy showed a massive pulmonary embolus of the type coming from the deep veins of the legs. There were two old small infarcts in the lungs

8. Veal, J. R.: The Prevention of Pulmonary Complications Following Thigh Amputations by High Ligation of the Femoral Vein, J. A. M. A. **121**: 240 244 (Jan. 23) 1943.

9. Allen, A. W.; Linton, R. R., and Donaldson, G. A.: Thrombosis and Embolism: Review of 202 Patients Treated by Femoral Vein Interruption, Ann. Surg. **118**: 728 740 (Oct.) 1943.

In retrospect, we could have prevented his death by roentgen examination of the chest at the time of his first symptoms on the fourteenth postoperative day. This would have given us the true cause of the sudden change in his progress. Thrombectomy with femoral vein interruption at this time would have forestalled the massive embolus. Prophylactic bilateral venous interruption would have been justified at the time of, prior to or a day or two after his gastrectomy.

Much has been said recently regarding the advantages of early ambulation in postoperative patients. That this method of treatment has much to commend it we accept, and we make use of it in many cases. It does not, however, prevent thrombosis of the leg veins in all instances, but our future data may show reduction in this complication on this basis.

In a 78 year old mother of a physician we were asked to repair an umbilical hernia that had recently become incarcerated during a bout of coughing associated with acute bronchitis. The hernia could be kept reduced by careful strapping, and this was done until all acute pulmonary symptoms had subsided. A repair of the hernia was then done under spinal anesthesia with interrupted number 30 cotton sutures. The patient was cerefully nursed and, in addition to passive exercises of the legs and pressure bandages, the patient was got out of bed several times daily after the first postoperative day. On the evening of the eighth day a slight swelling was noticed in the left foot. There was no elevation of temperature and no evidence of tenderness over the deep veins of the leg. The superficial veins were not dilated. The next morning the calf measured 2 cm. greater on the left side and there was minimal discomfort in the calf muscles on dorsiflexion of the foot. At noon, eighteen hours following the first sign of phlebothrombosis, the femoral vein was exposed

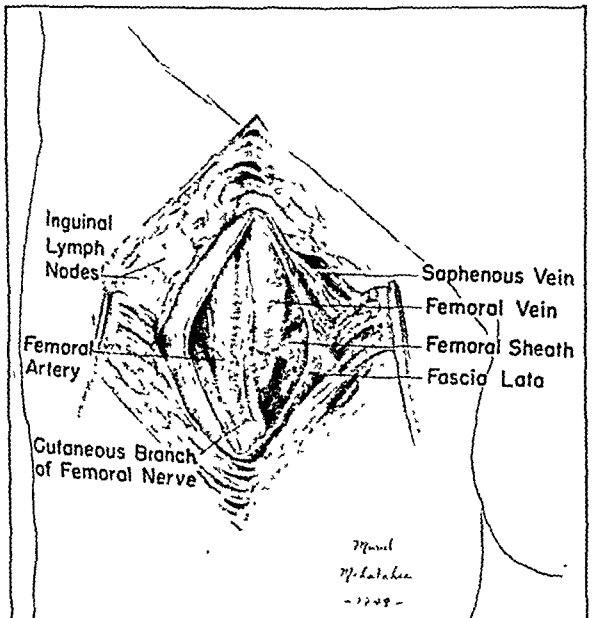

Fig. 2.—Schematic drawing to show the exposure of the femoral sheath. A vertical incision is used over the femoral vessels. This type of incision avoids severance of the lymphatics, since it parallels them. Note that the femoral vein lies medial and partially posterior to the femoral artery. The latter must be retracted lateralward to expose the vein. The saphenous vein is exposed but carefully preserved, provided it is not thrombosed. The inguinal lymph nodes are retracted lateralward.

under procaine anesthesia. On opening the vein a considerable amount of completely loose thrombus was removed by suction from the iliac as well as from the distal segment of the femoral vein. The superficial femoral vein was divided between ligatures and the wound closed. The patient had a low fever for three days, after which she was again made ambulatory and was discharged home on the twenty-first hospital day. The right vein was not interrupted, but this leg was carefully watched

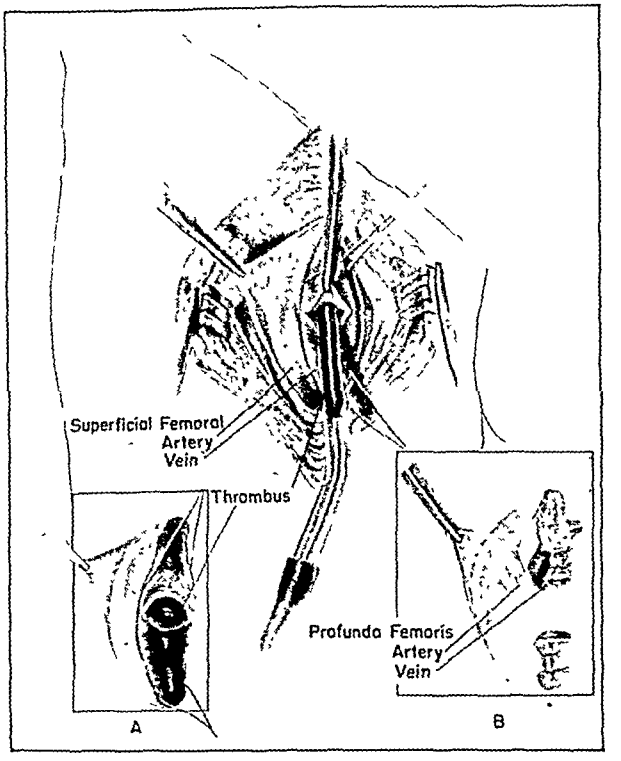

Fig. 3.—Schematic drawing to show the aspiration of a thrombus from the femoral and iliac veins through the superficial femoral vein. The cephalad segment is first cleared, then the distal one. The vein should not be ligated before aspiration of the thrombus. Note it in the glass cannula. (*A*) The inset shows the thrombus protruding through the transverse incision in the superficial femoral vein. Note the traction ligatures proximal and distal to the vein incision for control of the bleeding after thrombectomy. (*B*) The inset shows the ligation and division of the superficial femoral vein. Note the retraction of the vein ends. Each is ligated, then reinforced with stitch ligatures in each vein cuff distal to the primary ligature for additional safety against postoperative hemorrhage.

for any sign of thrombosis. She was seen one month after discharge with a barely perceptible amount of lower leg edema. Her only complaint was a slight swelling in the operative site from a small collection of lymph. This has absorbed and the patient has had no further complication.

Our experience with heparin in the treatment of thromboembolic disease has not been in accord with that of Murray.[10] In our clinic patients were apt to do well while heparinization was carried out only to have a recurrence of symptoms and signs after the heparin was stopped ten to fourteen days after its beginning. One patient died of a fatal embolus the day following two weeks of adequate heparinization. We have found this method of treatment of great value if repeated minor infarcts have occurred after femoral vein interruption. Also it is used routinely after any arterial surgery.

Dicumarol has been used cautiously in a small number of cases. We are of the opinion that this method of treatment may become sufficiently standardized to warrant its use more extensively. At this time, however, we do not believe that it is as safe or as innocuous as femoral vein interruption. Certainly this is true in our clinic during the pressure of war curtailment in laboratory control and experience of personnel.

10. Murray, G. D. W.: Heparin in Thrombosis and Embolism, Brit. J. Surg. 27: 567-598 (Jan.) 1940.

To June 1, 1944 we have interrupted the femoral veins for the treatment of, or the prevention of, thromboembolic disease on 464 patients. There has been no fatal complication as a result of this procedure in this entire series. Data are available for more detailed analysis on the 367 patients operated on before Jan. 1, 1944 and these are herewith presented.

That we have approached this form of treatment with caution but with increasing enthusiasm is indicated in table 3. The increasing incidence of bilateral femoral vein interruption as shown in table 4 has come about as a natural result of experience. So often have we had signs appear in the opposite leg or a new infarct occur a few days after unilateral interruption that we now feel that the two femoral veins should be interrupted at the same sitting. This has been further supported by the fact that the interruption of a normal femoral vein is harmless. Also we have found thrombosis in many opposite femoral veins that were thought to be normal by all our preoperative criteria. It is our present attitude to recommend bilateral femoral vein interruption routinely if either side is done. It is true that there is a slight predilection for thrombosis on the left side. This is indicated in table 5, which also includes the location of phlebotomy and interruption.

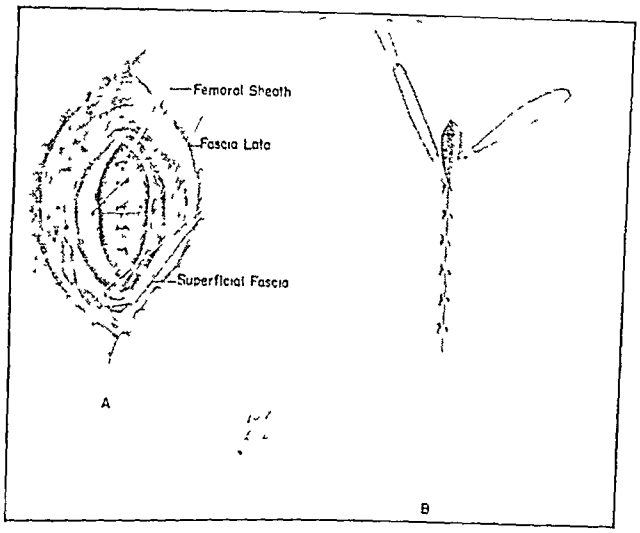

Fig. 4.—*A*, schematic drawing to show the closure of the femoral sheath, the fascia lata and the superficial fascia with interrupted sutures of fine cotton. *B*, schematic drawing to show the skin closure with interrupted vertical mattress sutures of fine silk.

This brings to mind the question of where the vein should be opened and interrupted. It has been our feeling that the superficial femoral vein just below the profunda femoris was the ideal site. This area is easily exposed and offers a segment of at least 2 cm. in length that is free of muscular branches. There is less danger of accidental hemorrhage in this area than in the common femoral vein. Thrombi can be removed from the iliac region adequately by suction through this approach. Although it is recognized that sublethal infarcts can occur from the saphenous or the profunda, we have not experienced a single instance of fatal embolus after interruption of the superficial femoral at the level used. Actually only 5 per cent of our patients have had infarcts of any degree following this procedure and most of them have been of minor importance. In a few instances these have been multiple and, when added to the damage already done by infarcts that had occurred before femoral vein interruption, have caused serious alarm. It is in this type of patient that heparin has occasionally been used with definite benefit. We have supposed that many of these post-vein interruption infarcts have come from the iliac region where thrombi may have recurred or in cases in which the removal by suction has been incomplete.

One of us (R. R. L.) has favored interruption of the common femoral instead of the superficial femoral

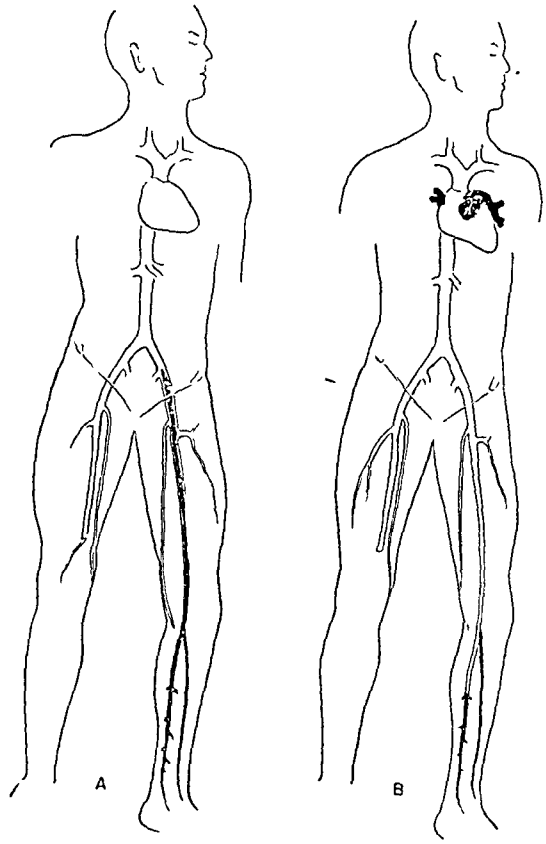

Fig. 5.—*A*, schematic drawing to show a bland thrombosis of deep veins of the left lower extremity. Note that the thrombus is attached to the femoral and iliac veins. *B*, schematic drawing show the free portion of the thrombus coiled in and occluding the monary artery, producing fatal pulmonary embolism. This catastr can be prevented by thrombectomy and femoral vein interruption

during the past year. He feels that in rare instanc the profunda femoris may unload sufficient thrombus produce a lethal outcome, particularly in the patie who has already had massive, repeated or subleth emboli. He has no proved instance of this occurrence but believes it is a possible explanation of one fatality in his experience. He recommends that the interruption be made below the saphenous if it is patent, since interruption above the profunda and including the

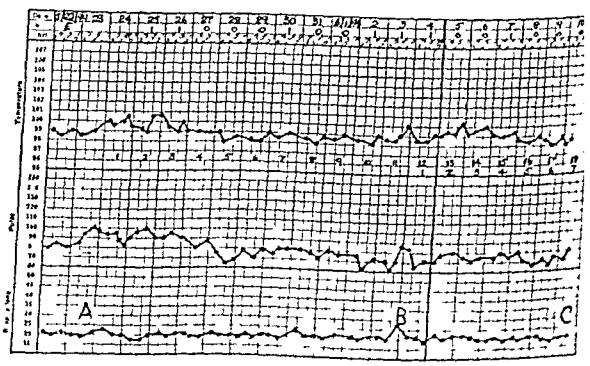

Fig. 6.—Temperature, pulse and respiration. *A*, combined abdominoperineal resection; *B*, bilateral femoral ligation, *C*, discharge

saphenous has caused venous congestion of a troublesome degree in a few instances It is admitted that interruption of the common femoral is technically more difficult to accomplish. Because of muscular branches in this segment, hemorrhage is harder to control. Also this feature makes it necessary to ligate in continuity after phlebotomy and thrombectomy There may be no advantage in division of the vein as we have practiced it in the superficial femoral, but the obvious elimination of tension on the vein when divided may well have a beneficial influence on the final result

Indications of venous thrombosis are multiple Often chest pain is the first warning, while in many instances the routine bidaily examination of the legs may reveal a clue. The clinical chart may offer the first evidence of thrombosis and infarcts. The patient less often complains of discomfort in the foot or calf muscles. Chest pain appearing suddenly, often associated with uncomfortable deep breathing and cough with blood tinged sputum, is so characteristic that confirmatory roentgenograms are unnecessary Often, however, infarcts occur that give no sign or symptom but are

easily seen in the x-ray film of the chest Ninety-five per cent of these infarcts are in the lower lobes and 55 per cent are in the left lower lobe (table 6).

Thirty-eight per cent of our cases presented chest symptoms first, while 62 per cent evidenced the initial difficulty by one of the leg signs or symptoms The latter include pain, swelling, tenderness or dilated superficial veins Homans has called attention to the dorsiflexion sign, which is pathognomonic when present This test is carried out by gentle but forceful dorsiflexion of the foot with the leg extended If discomfort in the calf muscles or the popliteal space is experienced during this maneuver, one can be sure that deep venous thrombosis exists Forty one per cent of our cases examined in this manner showed a positive Homans sign Sixty-six per cent showed swelling of the extremity in some degree Two thirds of the cases examined for tenderness over the calf muscles or deep veins gave this evidence of thrombosis

We have noted a typical change in the clinical chart when thrombosis and infarct have occurred even without symptoms. If one observes a slight rise in temperature, pulse and respiration on the same recording, then a thrombosis and infarct has occurred. This sign was found to be a reliable guide as to treatment in approximately 78 per cent of the charts suitable for analysis. In many instances one may get an elevation of one or two of the three lines for other reasons, but if they occur synchronously one must assume that the thromboembolic syndrome has occurred.

Total right and left	579	100 0

The use of phlebograms in our clinic, once believed to be so important,[11] has gradually been discarded. This has come about as a natural result of experience. Phlebograms require a special time consuming technic and much practice in the interpretation of the films. Owing to the pressure of work and rapid changes in personnel, it became obvious to us that other criteria were less time consuming and more reliable.[12] During the year 1943 we used phlebograms in only 3 instances. One of us (R R. L) believes that phlebography is not innocuous and that this procedure may have been responsible for thrombosis in some instances and fatal embolism in 1 case with phlebograms interpreted as negative for thrombosis. He therefore feels that if phlebography is done, regardless of its interpretation, one is committed to femoral vein interruption

Morbidity following femoral vein interruption is less than we expected. The average number of days from this procedure to a normal chart was 5.3. This means that early rising can be safely carried out Some of the patients have been kept ambulatory in spite of a slightly elevated chart, but this has not been the rule Patients were discharged from the hospital in an average of 8 9 days following femoral vein interruption.

In the series of 367 cases analyzed there were only 5 instances of wound infection. This is particularly surprising when one considers the location of the

wound and the more or less emergency nature of the operation Instruments, gloves, gowns and drapes are changed before the second side is done.

Hemorrhage from the slipping of a ligature has occurred in 3 cases. This accident is unwarranted and will not occur if a stitch ligature is used distal to the original tie. If this complication arises, it is best to

return the patient to the operating room, remove the hematoma and properly secure the vessel.

Lymphorrhea has occurred in 15 instances. This is troublesome but soon ceases of its own accord. Patients having this complication are kept in the hospital until their wounds are dry. One may keep this complication at a minimum by carefully making the incision through all tissue parallel to the vessels. Often dissection mesially to ascertain the location of the saphenous is unnecessary. At times one can identify and ligate a transected lymphatic vessel. There have been an additional number of wounds that have filled to some extent with lymph, without actual discharge of this fluid from the wound. It is best not to aspirate this collection; if left alone, it will be absorbed in three to five weeks. Much of this can be avoided by carefully closing the deeper tissues with fine interrupted cotton sutures.

There have not been any deaths in the group of 464 cases reported as the result of femoral vein interruption.

† The fatal embolism in this case originated from the uninterrupted right femoral vein.

OPERATIVE TECHNIC

Under local infiltration 1 per cent procaine hydrochloride anesthesia, a 4 inch incision is made from the crease of the groin distalward along the course of the pulsating femoral artery. The skin edges are carefully protected by sterile towels. The dissection is carried through the fat and superficial fascia to the vascular bundle. The femoral artery overlies the vein somewhat in this region and is freed sufficiently so that it can be retracted laterally. The center of this wound exposes the superficial femoral vein, which can be dissected sufficiently to identify its main branches in this region. If the saphenous vein is normal, it is left alone; if it is thrombosed, it is interrupted. Having identified the profunda femoris, the superficial femoral is freed on its posterior avascular segment approximately 2 cm. distally. Under this is passed two strands of 0 chromic catgut or number 30 cotton. These are held by hemostats at the proximal and distal ends of the free segment. The center of this segment of the superficial femoral vein is then incised transversely through half its diameter. If the thrombus has extended to this level, it begins to extrude itself. Suction is applied through an angulated glass tube and the proximal vein freed of thrombi until free bleeding occurs. The upper control ligature is then tied. The distal segment of vein is then cleared of thrombus as well as possible by the suction tube. The more adequately this is accomplished, the freer the bleeding. This end is now tied and the vein completely divided. Stitch ligatures are then applied through the cut ends distal to the ties. The wound is irrigated with isotonic solution of sodium chloride and closed without drainage. Woven bandages are applied to the foot and leg up to the knee. These are advocated during ambulation as long as there is swelling or as long as it gives the patient comfort.

It is interesting to note that patients who have had infarcts before femoral vein interruption are less likely to have thrombi at the site of operation than those who are operated on before infarcts occur. The ideal situation is to make the diagnosis on minimal leg symptoms and signs, thereby interrupting the vein above the thrombus. Certainly the earlier this is done the shorter

the convalescence, both immediate and ultimate. Fever is dependent mainly on a pathologic condition of the lung in the form of infarct, but in many instances the inflammatory reaction about the vein itself plays a role. All the patients have some swelling of the leg after vein interruption and a few of them develop swelling of the thigh. This will last a variable time. If the operation is done for minimal signs early, the postoperative swelling is almost imperceptible. If the thrombus is such that it can be completely cleared out, the swelling lasts only a short time. The longer the process has existed in the vein, the longer it takes for all the postoperative edema to subside. The average patient will discard bandages in from four to twelve weeks. Occasionally these will be worn for six months. We have seen only 1 instance of postphlebitic phlegmon and ulcer so frequently seen in spontaneous recovery from thrombophlebitis. In this case phlebothrombosis had occurred with repeated infarcts diagnosed as recurring pneumonia over a period of six months prior to thrombectomy and femoral vein interruption.

It should be mentioned that inferior vena cava ligation has been done in 10 cases by one of us (R. R. L.). These were for iliac thrombosis of considerable standing with repeated infarcts. It is simpler to expose the vena cava through an abdominal incision without entering the peritoneum, since this structure can be reflected intact with ease, especially from the right. This procedure is preferable to bilateral iliac interruption, which creates technical difficulties and has been done at two sittings through elongated ureteral-like exposures. If the thrombus is of long duration it is unlikely that it can be successfully aspirated through a femoral exposure. Although this has been done several times, the resulting sublethal infarcts have been troublesome and the postoperative edema has been of long duration. It is surprising to see the rapid subsidence and the minimal edema following vena cava ligation in the cases treated by this method.

SUMMARY AND CONCLUSIONS

1. Bilateral femoral vein interruption is a safe procedure which can be carried out on extremely ill patients and will prevent massive fatal pulmonary embolism.

2. This operation should be carried out (1) on patients who have developed nonfatal pulmonary embolism, even though no positive signs of venous thrombosis in the legs can be detected, and (2) on any patient who develops phlebitis, as evidenced by pain, tenderness, swelling in the lower extremities, dilated superficial veins or pain in the calf muscles when the foot is forcefully dorsiflexed (Homans' sign). It is rare that all these signs are present, so that the decision to operate may depend on one or two criteria.

3. Bilateral femoral vein interruption, *if any is done*, is indicated on all patients except on very rare occasions. This is because in a number of instances thrombus formation has been found present in the apparently normal unaffected extremity.

4. Femoral vein interruption has been used prophylactically without harm for a few elderly patients with intertrochanteric fractures of the hip and in some requiring major abdominal surgery for cancer.

5. Every attempt should be made to make the diagnosis of thrombophlebitis before the femoral and iliac veins have become involved, since by early treatment the postoperative sequelae are reduced.

6. In cases with femoral-iliac thrombosis, the mechanical removal of thrombus from the vein by aspiration has been demonstrated to be a safe procedure. It should be done as early as possible after the thrombosis has been diagnosed. This reduces the pain and swelling in the leg and hastens the recovery, in addition to preventing massive fatal pulmonary embolism.

7. No deaths have occurred in the group of 464 cases reported as the result of femoral vein interruption.

8. The morbidity of thromboembolic disease is tremendously reduced by this operation.

ABSTRACT OF DISCUSSION

DR. ALTON OCHSNER, New Orleans: At one of the recent surgical society meetings, a new operation was described for the removal of a pulmonary embolism. We all know what happens when a person develops a pulmonary embolism, and if he is sick enough to be operated on the result is almost invariably a fatality. There is only one treatment for pulmonary embolism and it is prophylaxis. A great deal can be accomplished by preventing the clot originally, as the authors have emphasized. It is my belief that every patient past 45 years of age who has to be operated on should have his extremities wrapped from his toes to his groin before he goes to the operating room. This wrapping is maintained during his postoperative period until he is able to move his extremities actively. Early ambulation has undoubtedly done a great deal to cut down the incidence of postoperative thrombosis. Dr. Allen has referred to the geographic incidence of this condition. It is true. In the South we see a great deal less of it. Another factor is undoubtedly the temperature. It has been shown that in the Northern clinics, as Dr. Allen and his associates showed today, the incidence of thrombosis is higher in the winter months. I believe that this is probably due to the vasospastic influence, which is more likely to occur during the winter months. The patient who has a true thrombophlebitis does not require a vein ligation, and injection of sympathetic ganglions with procaine is all that is necessary. On the other hand in the presence of a hard thrombus, i. e. phlebothrombus, in which the clot is not firmly attached, prophylactic ligation of the vein is essential. In this way embolism is prevented. In older persons we routinely look at their extremities, look for tenderness in the calf and the plantar veins, determine the Homan dorsiflexion sign and look for tenderness along the course of the femoral vessels. Whenever tenderness is present or whenever there is an elevation of pulse rate out of proportion to anything else, we suspect intravenous clotting and will tie them up. I believe, as Dr. Allen does, that phlebography hasn't the place that we originally thought it did. It is nice to demonstrate the presence of a clot, but probably it is best to ligate the femoral and then one can be sure in a suspected case. The bilateral ligation should certainly be done in most cases.

DR. ARTHUR W. ALLEN, Boston: Heparinization requires the patient to be pretty well confined to the hospital bed or, certainly, to the hospital room. Now, the prophylactic use of heparin and dicumarol has a real future. We are observing it carefully and cautiously. We have had no serious sequelae with the use of dicumarol given in small doses shortly after operation and carried on afterward. In our city Dr. George Van S. Smith has routinely given his elderly patients 200 mg. of dicumarol after operation, repeated in five days, and occasionally a third dose is given. He has made a careful check on these patients and we can depend eventually on his report, which he is not quite ready yet to make. The only difficulties he has had have been hemorrhage in the vaginal plastic operations. These have been troublesome, sometimes requiring subsequent repair. There have been no serious abdominal hemorrhages in his group so far. Dr. Smith believes now that he has reduced the incidence of thromboembolic disease a great deal, probably as much as 75 per cent. When we can get the use of this drug standardized we shall find it tremendously helpful and possibly we can avoid many of these simple and innocuous surgical procedures which I have described.

SINGLE INJECTION TREATMENT OF GONORRHEA WITH PENICILLIN IN BEESWAX-PEANUT OIL

RESULTS IN 175 CASES

CAPTAIN MONROE J. ROMANSKY
MEDICAL CORPS, ARMY OF THE UNITED STATES

CAPTAIN ROBERT J. MURPHY
MEDICAL CORPS, ARMY OF THE UNITED STATES
AND
TECHNICIAN (3D GRADE) GEORGE E. RITTMAN
MEDICAL DEPARTMENT, ARMY OF THE UNITED STATES

In previous reports [1] two of us have described a method for prolonging the action of calcium penicillin by suspending it in beeswax-peanut oil and have shown successful results attained in a small group of patients with gonorrhea by a single injection of this mixture.

Our purpose here is to give the results obtained in the treatment of 175 cases of gonorrhea in males by a single injection of penicillin beeswax-peanut oil. The excellent results in the treatment of gonorrhea with penicillin in saline solution and the various methods and schedules of utilization have been reported by others.[2]

In our first reports [1] a suspension of penicillin beeswax-peanut oil was obtained by shaking the mixture for ten to fifteen minutes by hand. We have since used a mechanical blender, which has proved more efficient and practical for preparing larger quantities. It is necessary to emphasize that the preparation of a satisfactory penicillin beeswax-peanut oil mixture is contingent on the use of calcium penicillin, highly refined peanut oil and bleached U. S. P. beeswax.

The peanut oil is sterilized by the following procedure: It is first Seitz filtered, then passed through six layers of sterile gauze or a sintered glass filter, and finally autoclaved at 17 pounds of steam pressure for twenty minutes. The beeswax is heated to a liquid state and filtered through six layers of sterile gauze. It is then autoclaved at 17 pounds of steam pressure for twenty minutes. The most satisfactory mixture used in this study was 100,000 units of calcium penicillin in 1 cc. of 4 per cent (by volume; 3.2 per cent by weight) beeswax in peanut oil. This can be prepared in the following manner: The desired quantity of penicillin is placed in the sterile mechanical blender or mixer, and to this is added 1 cc. of a sterile 4 per cent mixture of beeswax in peanut oil for each hundred thousand units of penicillin. Prior to adding the beeswax-peanut oil, it is heated until clear. The mixture is then blended until the penicillin is completely suspended in the beeswax-peanut oil. At this time the mixture is sufficiently liquid so that it will not only pass through a 19 or 20 gage needle but will even go through a 26 gage needle. Sodium penicillin in beeswax-peanut oil has not produced as satisfactory a mixture or as consistent results as the calcium penicillin. Therefore its use is inadvisable for the present.

Detailed studies on the absorption and excretion of 200,000, 250,000 and 300,000 units of penicillin in 1 cc. of beeswax-peanut oil will be reported later.

Studies on the stability [1] of penicillin in beeswax-peanut oil will also be reported later. However, assay of this material, which has already been maintained at ice box, room and 37 C. temperatures for six months has shown no loss of potency.

Additional follow-up [1] on the gross and microscopic studies of the tissues from the site of the injection of the mixture shows minimal residual findings at five months in hamsters and two and one-half months in rabbits. Details on these results will also be reported.

The cases of gonorrhea in this study were treated by both the hand shaken and the mechanically blended mixtures of penicillin beeswax-peanut oil. Table 1 shows

the various combinations of the penicillin mixture used in the single injection treatment of 175 cases of gonorrhea in males.

Of the 100 patients who received a single injection of 100,000 units, 85 had penicillin assays [3] of the blood determined at intervals of one hour for ten hours. Assays of penicillin in the urine were also done to determine for how long a period penicillin continued to be excreted. In this group of patients the average duration of assayable penicillin in the blood was seven and one-half hours. The average highest level in the blood was 0.156 Oxford unit of penicillin per cubic centimeter. The average duration of excretion of penicillin in the urine was twenty-four hours.

By contrast, a single injection of 100,000 units of penicillin in saline solution will produce a very high initial blood level of penicillin in the first hour, which rapidly diminishes to a vanishing point in four to four and one-half hours, with excretion of penicillin in the urine continuing for only six to eight hours.

From the Penicillin Section, Laboratory Service, and Medical Service, Walter Reed General Hospital.

Technical assistance was rendered by Technician (4th Grade) Minna Levy, Miss Dorothy Talbot, Technician (5th Grade) George W. Saip, Staff Sergeant Leslie H. Wood, Technician (4th Grade) Walter S. Eccard, Sergeant William J. Moon and Sergeant Herman Tanner.

Dis. **27**: 525 (Sept.) 1943. Herrell, W. E.; Cook, E. N., and Thompson, L.: Use of Penicillin in Sulfonamide Resistant Gonorrheal Infections, J. A. M. A. **122**: 289 (May 29) 1943. Sternberg, T. H., and Turner, T. B.: The Treatment of Sulfonamide-Resistant Gonorrhea with Penicillin Sodium, ibid. **126**: 157 (Sept. 16) 1944. Murphy.[5]

3. Assays of the blood were done by the method of C. H. Rammelkamp (Proc. Soc. Exper. Biol. & Med. **51**: 95 [Oct.] 1942) with minor modifications. The penicillin assays of the urine were done by the methods of Rake and Jones (ibid. **54**: 189 [Nov.] 1943) and of Rammelkamp.

Sixty of the 75 patients who received a single injection of 150,000 units had penicillin assays of the blood determined at intervals of one hour for twelve hours and had penicillin assays of the urine determined. In this group of patients the average duration of assayable penicillin in the blood was ten hours. The average highest level in the blood was 0.204 Oxford unit of penicillin per cubic centimeter. The average duration of excretion of penicillin in the urine was thirty-two hours.

TABLE 2.—*Time Interval for Change from Purulent to Mucoid Urethral Discharge in Gonorrhea Treated with a Single Injection of 100,000 Units of Penicillin in Beeswax-Peanut Oil*

Hours	2	4	5	6	7	8	10	12	18	24	36	48	72
Cases	5	13	3	17	6	16	7	16	6	6	2	2	1

The in vitro susceptibility[4] of the gonococcus to penicillin was determined in 52 patients. The range of susceptibility to penicillin was 0.0039 to 0.0625 Oxford unit per cubic centimeter.

All the 175 cases of gonorrhea treated gave definite clinical signs of urethritis with a frank urethral discharge. In addition, all cases gave a positive smear and culture for the gonococcus prior to the institution of therapy. All individuals admitted to the hospital for gonorrheal infection were treated regardless of the length of time the disease was present or whether previous treatment had been administered. No attempt at selection was undertaken, and no other treatment, either local or systemic, was given to patients receiving the single injection of penicillin in beeswax-peanut oil. All patients were confined to the hospital during their treatment and follow-up period to determine their cure, thereby eliminating any possibility of confusion between treatment failures and reinfection. The period of observation in all instances was a minimum of two weeks from the time of injection of penicillin in oil. Patients were inspected daily during the period of observation, and prostatic smears and cultures were done at two, four and seven days. This period of observation and the intervals at which cultures were obtained were based on previous experience[5] with the use of penicillin in saline solution in the treatment of gonorrhea. In addition, smears and cultures were taken from the third through the seventh hour after the injection of penicillin in oil in order to determine at what hour they might become negative. Duplicate cultures, to which had been added penicillinase (Clarase) were also taken in order to eliminate the possibility of inhibition of growth by penicillin which might be present in the secretion.

TABLE 3.—*Time Interval for Cessation of Mucoid Urethral Discharge in Gonorrhea Treated with a Single Injection of 100,000 Units of Penicillin in Beeswax-Peanut Oil*

Hours	24	48	72	96	120	168
Cases	21	11	32	16	10	3

The first group of 100 patients was treated by a single injection of 100,000 units of penicillin in beeswax-peanut oil. Injections were given in the upper outer quadrant of the buttock. Table 1 indicates the various volumes of the mixture and percentages of beeswax used. Of the 100 patients, 76 were white and 24 Negro. Seventy-one had had no previous treatment, and 29 were sulfonamide resistant. Ninety-three of the 100 patients were cured by the single injection. Seven required retreatment with a single injection of 150,000 units of penicillin in beeswax-peanut oil and were cured. Five were white and 2 Negroes; 2 of the white and 1 of the Negro patients had been sulfonamide resistant.

Of particular interest from the clinical standpoint was the rapid change from a purulent yellow urethral discharge to a scant, watery, mucoid type, as shown in table 2.

Eighty-three per cent showed this change in twelve hours and 95 per cent by twenty-four hours. The remaining 5 per cent changed by the seventy-second hour. Included in table 2 are the 7 failures with 100,000 units. These 7 cases also changed from a purulent to a mucoid discharge from one to twelve hours after their injection.

TABLE 4.—*Time Interval Between Treatment and Bacteriologic Negativity in 93 Cases of Gonorrhea Treated with a Single Injection of 100,000 Units of Penicillin in Beeswax-Peanut Oil*

Cases	1	4	1	1	
Bacteriologic negativity					
Hours	3	4	6	7	24
Cases	2	1	1	1	2

The 93 patients cured by the single injection of 100,000 units had complete cessation of the mucoid discharge, as shown in table 3.

At the end of a three day period following the institution of treatment 66.8 per cent were entirely negative for evidence of mucoid discharge, by the fifth day 96.7 per cent and by the seventh day the remaining 3.3 per cent. In the 7 cases which were failures a recurrence of the purulent discharge was present in forty-eight to seventy-two hours.

Of the 100 patients 79 per cent were bacteriologically negative within seven hours after the single injection of penicillin in oil (table 4) and 14 per cent were negative within seven to forty-eight hours. The remaining 7 per cent in this group of 100 patients receiving 100,000 units were the failures mentioned. These 7 were bacteriologically positive forty-eight hours after their injection. Subsequently they responded to a single injection of 150,000 units of penicillin in beeswax-peanut oil. Table 5 shows in these 7 cases the changes from purulent to mucoid discharge, the cessa-

5. Murphy, R. J.: Experimental Use of Penicillin in Treatment of Sulfonamide Resistant Gonorrhea, Bull. U. S. Army M. Dept., August 1944, no. 79, p. 101.

tion of the mucoid discharge and the hours at which the smears and cultures became negative. Contrasted with these findings, the treatment of gonorrhea with a single injection of 100,000 units of penicillin in saline solution resulted in only 74 per cent cure.[6]

Group 2 consisted of 75 patients who received a single injection of 150,000 units of penicillin in beeswax-peanut oil. In this group there were 54 white and 21 Negro patients. Sixteen of the 75 were sulfonamide resistant and 59 had had no previous treatment. There were no failures in this group of 75 patients receiving 150,000 units of penicillin in beeswax-peanut oil. The purulent urethral discharge became mucoid, as shown in table 6, within seven hours in 73.3 per cent of the cases, twelve hours in 92 per cent and twenty-four hours in 100 per cent.

The time required for the mucoid discharge to subside entirely in these 75 cases is illustrated in table 7,

in which 85.3 per cent showed this change in two days and 94.6 per cent in four days, with the remaining 5.4 per cent free from discharge by the seventh day.

Of the 75 patients, 82.6 per cent were bacteriologically negative within seven hours, as shown in table 8. The remaining 17.4 per cent in this group were negative within seven to forty-eight hours.

Of the 175 patients, 11 had severe acute prostatitis as evidenced by a greatly enlarged, exquisitely tender prostate. The smallest was twice the normal size, and the largest did not allow one digit of the examining finger to be introduced into the rectum. The effect of penicillin in oil on such complications appeared to be quite dramatic. Following the institution of treatment, in every instance, the prostate was about 25 per cent reduced in size by the end of the second day and 75 per cent reduced at the end of four days. By the seventh day culture the prostate had returned to its normal size. The response of prostatitis was much more striking than in cases previously treated with intermittent doses of penicillin in saline solution.

6. Leifer, William: Personal communication to the authors.

Three patients with epididymitis had complete relief from pain the day following treatment. However, it was not felt that there was more rapid reduction in swelling than in patients treated with penicillin in saline solution.

COMMENT

Striking features in the treatment of these patients with penicillin in beeswax-peanut oil were the rapid disappearance, usually within seven hours, of the subjective symptoms, especially frequency and pain on urination, the rapidity with which the purulent discharge became mucoid and disappeared, and the early attainment of bacteriologic negativity.

The degenerated coccoid organisms which have been described[7] were usually found in the smears which were taken in the third to the seventh hour.

The fact that the duplicate culture plates containing penicillinase yielded the same results as the regular culture plates indicated that if penicillin was present in the secretion obtained in the third to the seventh hours it was in insufficient quantities to inhibit the organism's growth on culture mediums.

The injection of the penicillin in beeswax-peanut oil produced no immediate discomfort. Twenty-four hours following the injection slight soreness was present to pressure, but this was gone within forty-eight hours. In none of the patients in this series were there any allergic manifestations to the mixture. No history of sensitivity to peanuts was obtained. Further allergy studies, including skin and patch tests on patients who have received the penicillin in beeswax-peanut oil and on a control group, are being carried out.

Approximately 30 patients in this group had complete hematologic studies including bleeding, clotting and prothrombin times. In addition, studies of the urine prior to the injection of the mixture and for seven days subsequently were obtained. These studies revealed no adverse effects from the penicillin in beeswax-peanut oil.

It may be noted in passing, in view of studies which are now being conducted, that single daily injections of penicillin in beeswax-peanut oil have also proved effective in pneumonia, impetigo, staphylococcic infections and other conditions which respond to penicillin in saline solution.

In addition, it is not inconceivable that a large enough single injection, such as 300,000 units or more, given at the time gonorrhea appears, might prevent the development of syphilis in cases exposed to the two diseases simultaneously.

SUMMARY

1. One hundred and seventy-five cases of gonorrhea in males were treated by a single injection of calcium penicillin in beeswax-peanut oil. There were no failures among 75 patients receiving a single injection of 150,000 units. Ninety-three of the 100 patients who received a single injection of 100,000 units were cured. The remaining 7 who received 100,000 units were failures and responded to a second single injection of 150,000 units of penicillin in beeswax-peanut oil.

2. A single injection of 100,000 to 150,000 units of calcium penicillin in beeswax-peanut oil will produce and maintain assayable levels of penicillin in the blood

7. Miller, C. P.; Scott, W. W., and Moeller, V.: Studies on the Action of Penicillin, J. A. M. A. 125:607 (July 1) 1944.

for seven and one-half to ten hours, with excretion of penicillin continuing in the urine for twenty-four to thirty-two hours.

3. The penicillin in beeswax-peanut oil mixture has produced no abnormal reactions locally or constitutionally.

PYELITIS OF PREGNANCY

FOCI OF INFECTION IN ITS PREVENTION

N. SPROAT HEANEY, M.D.
AND
HERMAN L. KRETSCHMER, M.D.
President, American Medical Association
CHICAGO

For a long time we have been impressed by the fact that with the passing of the years we see fewer and fewer cases of pyelitis of pregnancy. When we first started out in practice, pyelitis of pregnancy was a frequent as well as a disturbing complication for which urologic consultation was often requested, and the patients were usually extremely ill.

In order to verify our impressions regarding the incidence of pyelitis of pregnancy in the Presbyterian Hospital of Chicago, the records of the obstetric department for the past ten years were reviewed. During this time 9,802 deliveries took place and there were 31 cases of pyelitis. This study gave us an incidence of only 0.3 per cent: this is the lowest figure with which we are familiar. Crabtree [1] presents a table in which the incidence varied from 0.8 to 16.3 per cent.

Early studies disclosed that all patients with pyelitis of pregnancy had pronounced dilatation of the upper urinary tract. To ascertain whether dilatation was present only in such pregnant women as developed pyelitis or whether dilatation of the urinary tract was commonly present during normal pregnancy, Kretschmer and Heaney [2] studied the urinary tracts of 19 cases of normal pregnancy by means of retrograde pyelograms. All of these women were free of all signs and symptoms of urinary tract infection. In 47.36 per cent bilateral dilatation was found and in 35.84 per cent the kidney pelvis and ureter were dilated on one side only, while in 15.8 per cent no dilatation was found. In a later paper Kretschmer, Heaney and Ockuly [3] reported their findings in a similar study by means of intravenous urograms. In this series dilatation of the kidney pelvis and ureter occurred in 100 per cent of cases during pregnancy and the puerperium. A striking feature of the dilatation was that it was almost uniformly above the brim of the pelvis. This study, furthermore, showed that dilatation is progressive with pregnancy. There was one exception to this statement, in which the ureter was normal in advanced pregnancy when earlier it was dilated. Further, it was found that lateral displacement of the ureter, when found early in pregnancy, tends to increase as the pregnancy advances. In none of the cases studied did pyelitis develop during pregnancy, although pronounced dilatation and displacement was present.

Many reasons have been given to explain the dilatation. Increased intra-abdominal pressure, compression of the ureter by the presenting parts and pressure produced by the growing pregnant uterus are commonly used explanations. Some are satisfied by ascribing the dilatation to the hormones which at the same time produce the usual changes peculiar to pregnancy, the enlargement of the breasts, the softening of the pelvic structures and the enlargement of the vaginal tract. What the purpose and use of the dilatation of the urinary tract and increased bladder capacity, if due to hormonal action, is not clear. However, stasis of urine in the ureter and kidney pelvis results, and, whenever stasis in the body occurs, infection may result if the causative organisms are introduced.

At one time it was believed that the infection gained ingress from the vulva because of the shortness of the female urethra and that a cystitis occurred first and the infection then ascended the urinary tract.

In the light of modern knowledge we know that in systemic diseases bacteria frequently enter the blood stream and pass from the blood stream through the kidneys and are eliminated through the urine. When the kidneys are sound and the urinary tract is open, the organisms escape without injury to the urinary tract; but when obstruction to the urinary tract is present, pyelitis may result. We see pyelitis develop following acute colds and not infrequently during acute infectious diseases such as measles. Pyelitis in children's hospitals and orphanages following gastroenteritis is fairly common. We have seen pyelitis of pregnancy occur after acute food poisoning in which all members of a family had been equally sick but the pregnant mother became acutely ill of pyelitis because in her instance stasis of the urinary tract was present as a result of her pregnancy.

Billings and his associates many years ago directed the attention of the world to the role of foci of infection, particularly in the teeth and tonsils, in the production of disease in distant parts of the body. His work at first was with regard to arthritis and its cause. Experience and time demonstrated the major role that foci of infection played in the etiology of many previously obscure conditions. As our knowledge grew at the Presbyterian Hospital of the impressive role that foci of infection had to do with the production of systemic disease we instituted the routine eradication of foci of infection before elective surgical operations and at the beginning of pregnancy. We are quite certain that as a result of this routine we have seen postoperative mortality and morbidity reduced to a minimum. Postoperative wound infections, thrombosis and emboli, previously quite common, are now rarely seen. Postpartum breast abscesses and thrombophlebitis infrequently occur. Parallel with these decreases in postoperative and postdelivery morbidity, pyelitis of pregnancy has also been much reduced, and, since other factors in its causation remain the same, we cannot but attribute this reduction to the eradication of foci of infection in the teeth and tonsils of patients applying for obstetric attention.

Earlier we based our diagnosis of infection in the teeth on x-ray evidence of abscess formation or visibly loose or obviously carious teeth or stumps. Now we know that devitalized teeth, even though the x-rays

disclose no evidence of abscess formation, may nevertheless yield virulent organisms if after extraction the teeth are submitted to bacteriologic examination. Similarly we know that as soon as a tooth dies it may act as a focus of infection, though the x-rays reveal no pathologic changes. The electric pulp tester will occasionally disclose the presence of dangerous dead teeth that appear harmless and normal on ordinary clinical examination.

In the light of this more recently acquired knowledge it is possible that some of the earlier cases supposedly freed from foci of infection may nevertheless have owed their pyelitis to the existence of foci then not recognized or understood.

It is our purpose in this paper once again to reiterate the importance of the routine eradication of foci of infection in the preparation of women for expected pregnancy.

An analysis of the hospital records of the 31 patients who developed pyelitis was exceedingly interesting. In 2 patients the records were incomplete and in 2 others no foci of infection were recorded, leaving 27 case histories for consideration in this study. It is possible, as already stated, that foci were present but were either

Occurrence of Foci of Infection

overlooked with the methods used or for one reason or another not recorded in the histories.

It is to be noted that there were 17 patients with one focus, 4 with two foci, 3 with three foci, 2 with four foci and 1 with five foci.

Some of the patients came in when in labor; hence there was no opportunity for antepartum care.

We do not wish to present the various combinations of foci except to call attention to this possibility; hence in antepartum care one must bear this possibility in mind during the antepartum period.

In the accompanying table are listed the various foci found.

From the point of view of prevention of pyelitis of pregnancy these foci may be considered as chronic and intercurrent. The chronic lesions, provided the patient comes to the physician during the pregnancy and not in labor, can and should be removed. The acute intercurrent infections should, as far as possible, be prevented by appropriate management.

In conclusion, we are of the opinion that pyelitis of pregnancy is a preventable disease or, if not completely preventable, the incidence of its occurrence can be reduced to a minimum. We make this statement on the basis of our experience at the Presbyterian Hospital.

THE FEMALE URETHRA

THE CONNECTING LINK BETWEEN THE UROLOGIST AND THE GYNECOLOGIST

ALFRED I. FOLSOM, M.D.
AND
HAROLD A. O'BRIEN, M.D.
DALLAS, TEXAS

In discussing this subject with the Section on Obstetrics and Gynecology and the Section on Urology it would profit us both if we followed the admonition of the prophet of old who said "Come let us reason together." For we think that there are some fundamental misconceptions by both groups about what we would like to designate our connecting link, the female urethra.

We feel that we[1] and others (DeGraaf,[2] Virchow,[3] Johnson,[4] Caldwell,[5] Evatt,[6] Korinchevsky[7]) have proved that there exists a definite group of glands surrounding the posterior part of the female urethra, that this group of glands is identical in morphology, distribution, secretory activity and location with the male prostate and that in fact this group of glands should and will ultimately be spoken of as the female prostate gland just as we speak of the male mammary gland. In size the mammary gland in the male may be really infinitesimal as compared with some of the more luxurious adornments of the female torso yet, in fact, it is a miniature mammary gland. Just as the male breast is a homologue of the female breast, so also, in our opinion, is this group of glands the homologue of the male prostate gland.

Figures 1 to 5 will show that in the urethras here sectioned there exist gland structures in this region. Whether or not they shall be called prostatic is entirely outside the scope of this paper. The important thing is that this group of glands does exist. Some urologists have denied even the existence of glands in this region, but by now we believe that nearly all are agreed that they do exist, although some are not yet ready to call these glands the female prostate.

These glands do become infected in very early infancy and may remain infected for many years or even throughout life, producing a varied and at times a bizarre papillary posterior urethritis. Just how they become infected has not as yet been proved. In former contributions we have suggested that the infectious organisms reached the glands through the rather open funnel shaped, short urethral canal from the feces during the diaper stage. The infections of the cervix may and in some cases do have a part in keeping alive, if not actually producing, these infections.

This inflammatory urethritis may vary from a mild granular urethritis, as seen through the close visioned cystourethroscope (fig. 6), or may appear as a more definite papillary urethritis as in figure 7. The following

illustrations will show that this inflammatory reaction may vary from a mild infiltration as in figure 5 to a vicious inflammatory process as in figures 8 and 9. In some cases true prostatic calculi have been found.

From the foregoing we think it will be agreed at least that these women do have an active inflammatory process in their posterior urethras. This process may be acute, subacute or chronic. In many cases the urethral lumen is definitely strictured as shown by Stevens and others; and these strictures are an integral part of the pathologic picture we are trying to focus attention upon. The two processes, viz. the severe papillary or granular posterior urethritis and the stricture, go hand in hand to produce a pathologic clinical entity which can and does cause many women untold suffering.

There are two groups of clinical symptoms that are produced by this inflammatory posterior urethritis, bladder irritation and pain, and these two cannot be overemphasized; for so many women suffer from frequency, burning and some type of pain around the pelvis that it becomes of real importance to doctors dealing with women. These two groups of symptoms should be engraved on the mind in letters so bold and so bright

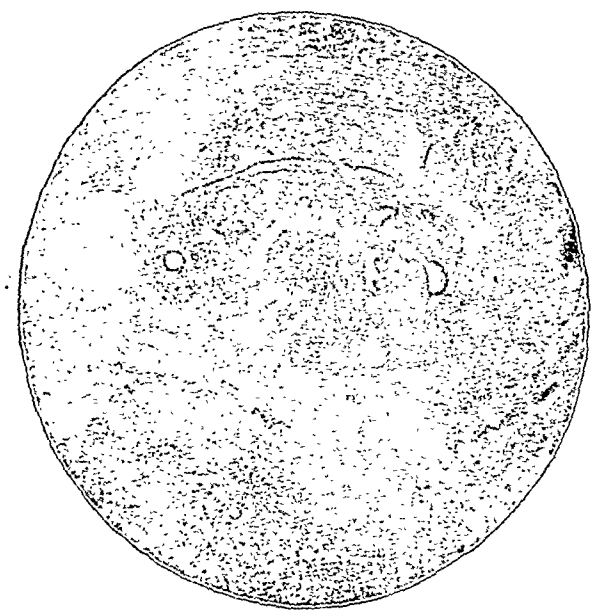

Fig. 1.—Section of full term fetus showing two lateral groups of glands.

that one can no longer fail to recognize that those irritable bladders and some pain it has not been possible to account for may have as their common denominator this inflammatory posterior urethra.

Many women suffer for years with either a continuous or a frequently recurring bladder irritation characterized by frequency and burning. These symptoms vary widely in different women; some are merely annoyed by occasional attacks of a mild degree, while others may have almost a constant frequency and burning which makes them miserable and, as one can well imagine, they get extremely nervous from this constant assault on their nervous systems.

In our experience, if we take all women who come to us for any urologic complaint, at least 90 per cent have this bladder irritation as one of the presenting symptoms, if not the main one. Of this group, 90 per cent have as the sole cause of this troublesome symptom complex an inflammatory urethritis. In spite of this, the urine in these cases is usually free from pus.

Some of these women have suffered for years and have consulted numerous physicians, gynecologists and urologists. They have had their bladders irrigated with solutions of every color of the rainbow, from the Stygian blackness of argyrol to the passionate light orchid of

Fig. 2.—Section showing numerous gland structures around posterior female urethra.

a pale potassium permanganate solution. They have been given the classic prescriptions of saw palmetto, bucu, juniper, potassium acetate and so on. But in spite of all the irrigations and medicines they go along getting no relief from anything.

Fig. 3.—High power view of section showing typical prostatic-like gland structures.

These patients remind us of the old woman in St. Luke who had suffered many things at the hands of many physicians, had spent all her money and instead of getting better rather grew worse.

Until a few years ago we urologists had overlooked these lesions in the posterior urethra of the female, and even now some of our brethren are not too intimately familiar with this very definite clinical and pathologic picture. These women have been told by some of the best urologists in the country that they had no pathologic

Fig. 4.—Section showing wide distribution of glands around posterior female urethra.

condition of the urinary tract, that their trouble was in their head and that they should go home and forget about it by getting interested in some form of outdoor exercise. One such woman so advised went home and started horseback riding. It did not take long to convince her that this form of diversion might be good for her mind but that bouncing around on her bottom with an inflammatory grass bur in the center of it was not so good.

Fig. 5.—Section showing periglandular inflammatory infiltration.

Through the years we have believed that, when some one came in complaining of a very definite trouble and always told the same story, one should be very loath to accuse such a patient of being neurotic. This is particularly true of these patients for, while they are terribly nervous, yet they have a definite cause for their nervousness. It is this ceaseless irritation that causes them to be nervous rather than the nervousness causing the irritation, for as far as we have observed there is no such thing as a nervous bladder.

Many women who suffer as we have outlined have had, or have been advised to have, a suspension of the uterus to lift it up away from where it was pressing on the bladder. The surgeon or gynecologist told them that the uterus had fallen forward so that it was pressing on the bladder and that this was the cause of their bladder irritation. In our judgment there is nothing more fallacious than this, because we have seen so many women who have had suspensions done for the relief of bladder irritation and then continued to have the same trouble until this urethral lesion was properly treated.

The Great Architect of our bodies did not make many errors in design, and He so placed the uterus that it must live in rather intimate association with the bladder; therefore its anterior surface must be almost constantly pressed against the bladder wall.

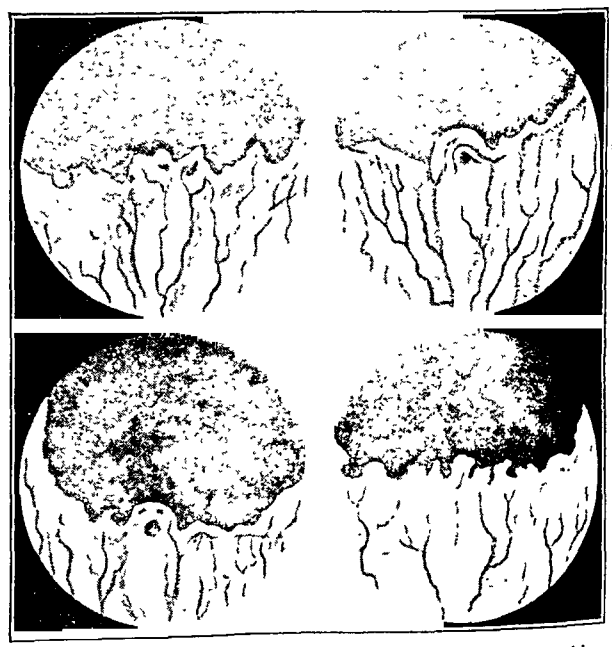

Fig. 6.—Cystourethroscopic view showing granular posterior urethritis.

Let us hasten to say that we are not by any means suggesting that suspensions should not be done for definite gynecologic reasons; but what we are saying is that if one is doing the suspension primarily to relieve a trying bladder irritation then we think that one is wrong; and one's failures will finally be cured by the alert urologists who find and clear up these inflammatory posterior urethras.

Repairs of cystoceles have also been done for the relief of bladder irritation. We feel again that if one has a definite reason for doing a cystocele operation it should certainly be done; but if one is doing the cystocele operation primarily to relieve the woman of bladder irritation one should first have the posterior urethra studied very carefully before operating; for in the great majority of such cases one will fail to get a result, not because one did a poor operation but because the real cause of the woman's trouble was not the cystocele but a chronic inflammatory posterior urethra. We have literally scores of these cases in our files, in which successful repairs of cystoceles have been done and the bladder irritation has continued. These patients had

this lesion of the posterior urethra, and when it was cleared up they were finally cured.

Once more we want to emphasize that we do not advise against cystocele repair—far from it—but, if one has only bladder irritation as an indication for the procedure, then we feel that one should stop, look and listen.

The next symptom produced by this inflammatory posterior urethritis is pain. This pain is a referred pain manifesting itself in various locations. These pains are, as a rule, dull and aching in character, but at times they may be so closely similar to renal colic in location and severity that it may be difficult for one to be sure one is not confronted with a true renal pain. A Frenchman, Civiale, in 1850 first called our attention to the fact that pains in and around the female pelvis may and can be caused by the urethra; but the dust of nearly a century had covered over his statement until we excavated it from the ruins and gave him due credit in a paper we wrote in 1934.

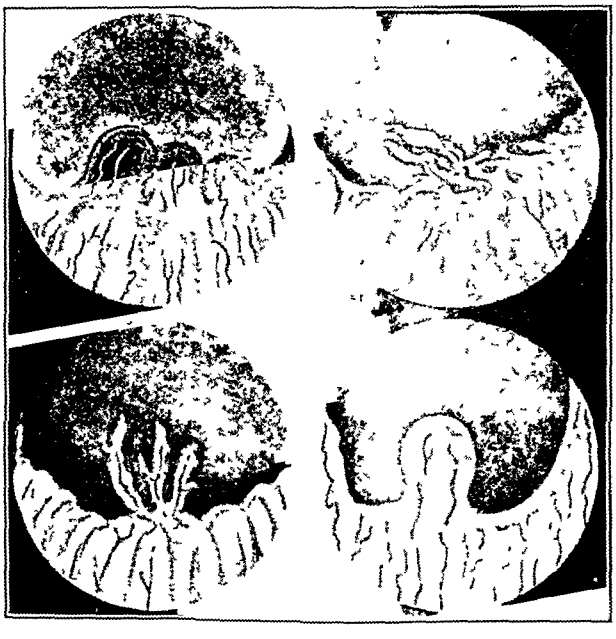

Fig 7.—Cystourethroscopic view showing papillary posterior urethritis

The most frequent sites for this referred pain are either (1) in the right or the left iliac region, low down, (2) the lumbosacral region of the back . . . and how many women have the backache there, (3) either loin, where if the pain is severe it may be, and has frequently been, mistaken for renal or ureteral disorder or (4) the inner side of the thighs. In fact, in recent years we have paraphrased one of Richard Cabot's famous dicta thus: "Any pain within 2 feet of the female urethra for which one cannot find an adequate explanation should be suspected of coming from the female urethra."

The pain most usually seen is in the iliac regions, and it is well known that any woman with a pain in either iliac region is in danger of being operated on by some good surgeon or gynecologist for some real or fancied pelvic disease. An appendix is not entirely safe under such circumstances, for an appendix may, as is also known, be found on the left side.

Our records are literally filled with women who have had, through the years, just two definite symptoms, bladder irritation and pain, in one of these locations. They have had from one to six or eight abdominal operations with absolutely no relief from either the bladder irritation or the pain. We have in a tremendous majority found these women to be suffering from a chronic papillary or granular posterior urethritis, and the correction of this trouble has almost uniformly given

Fig 8.—Anatomic specimen of bladder opened from above, showing internal urethral orifice filled with papillary structures

them relief, not alone from one, but from both complaints

As Bulwer-Lytton once asked in the title of his great English novel "What Will He Do with It?" so you already are asking What shall we do with it? The foundation work of the treatment of this troublesome pathologic condition is urethral dilations. This should be done twice a week regularly, beginning with the size sound that will stretch but not tear the urethral mucosa. Then the size of the sound should be gradually increased until a 30 or 32 F. will go easily. After each dilation we instil 10 to 15 cc. of 0.25 per cent solution of strong

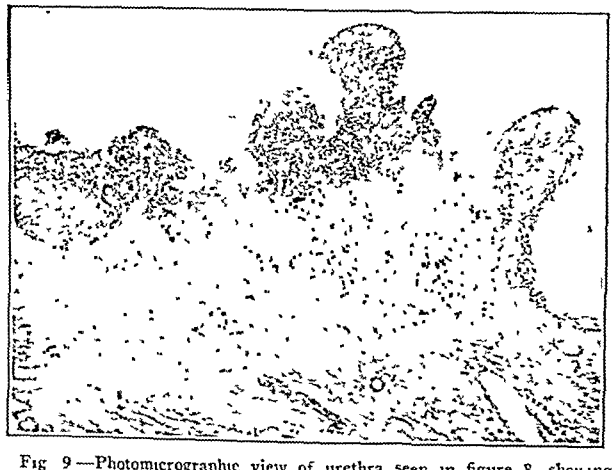

Fig 9.—Photomicrographic view of urethra seen in figure 8, showing intense inflammatory infiltration and replacement of normal transitional by stratified squamous epithelium.

protein silver. We really do not believe that this instillation has any virtue but out of respect to the ancient faith in solutions in the bladder we continue the practice.

When the urethra has been dilated for about six weeks, the next thing to do is to fulgurate some of the pathologic tissue in the posterior urethra. After this fulguration the patient is allowed to rest for two weeks.

Then the dilations are resumed and given for a period of six weeks to two months, when another fulguration may be done. This routine is followed until the patient is relieved and there is no further evidence of pathologic change present in the posterior urethra.

In some cases that are refractory to treatment one should never lose sight of the fact that there is a very intimate lymphatic connection between the cervix uteri and the posterior urethra and trigone. Hence these patients may be and often are helped by clearing up an old endocervicitis, which may have been playing a part in the perpetuation of the urethral infection.

These women have not been operated on by the wagonyard group of surgeons and gynecologists but by some of the best in either group; and we are not pointing the finger of scorn, as we live in too fragile a domicile. We are simply trying to point out that the female urethra is not the insignificant structure we have been taught to believe, but that it harbors a clinical and pathologic entity worthy of the most serious consideration.

REPORT OF CASES

Mrs. J. W. K., aged 44, white, who was examined Feb. 5, 1944, stated that for five years she had suffered from a dull aching pain in both iliac regions and the suprapubic area. Six months after the onset she was operated on and both tubes and a portion of one ovary were removed without any relief from her pain. One year later she was again operated on because of the pain. At this time some adhesions were broken up and some tissue removed but she does not know the nature of this; however, it did not affect the pains. She had to be catheterized several times after this operation and has had increased frequency of urination since then. Examination of the urinary tract was negative at this time. The patient then went to a clinic, where a third operation was done, this time releasing adhesions. Again her pains were not relieved, but in addition she developed a new pain in the region of the right kidney. This pain increased when the bladder was filled and was always relieved by voiding. During the past year she had become extremely nervous. Our examination revealed a tight urethral stricture with a pronounced chronic urethritis. There was immediate response to urethral dilations in that the patient felt definitely that she had less pain. Following the first fulguration she experienced a practically complete relief from her symptoms. The urethra was fulgurated again on June 4, 1944 and since then she has been completely comfortable.

Mrs. G. A. E., aged 46, white, first examined June 3, 1941, complained of suprapubic burning pain of many years' duration. In addition she stated that for over fifteen years she had suffered from repeated mild attacks of urinary frequency, urgency and dysuria with associated low lumbar backaches. The attacks would last from three to five days and recurred every three to four months. Because of the bladder irritation she felt that she had become increasingly nervous during the past two or three years. Examination revealed a stricture of the urethra size 14 French. In addition there was a pronounced chronic urethritis. The remainder of the urinary tract findings were normal. Urinalysis was negative. Following dilation of the urethra and fulguration of the urethral mucosa the patient has been entirely relieved of her trouble. There have not been any attacks of bladder irritation in three years.

Mrs. S. P., aged 57, white, first seen Oct. 1, 1941, for five years had been suffering from urinary frequency, dysuria, urgency and a lack of feeling of relief after voiding. About every three months the bladder symptoms would be increased in severity and she would have fever ranging from 101 to 103 F. and lasting three or four days. In 1940 she was treated for two months for a right ureteral stricture and after a rest for six months these dilations of the right ureter were again repeated without any relief from symptoms. Following this the urethra was fulgurated on two occasions, and later a "caruncle" was burned out. In spite of this her symptoms persisted. Two weeks before our examination she had gone through a typical attack of increased urinary symptoms and fever of three days' duration. The general physical examin tion was essentially normal. There was some distortion of tl external urethral meatus. The urethra was strictured so th a No. 20 French bulbous bougie passed with difficulty. In tl midportion of the urethra there were abundant granulations an a few papillary masses. The posterior urethra was clear, havin previously been fulgurated. The bladder was normal. Th left pyeloureterogram was normal. The right pyeloureterogra was normal except for slight angulation in the upper thir The bladder urine showed 10 white blood cells per high pow field. Urine from both kidneys was negative on microscopi examination.

The urethra was dilated twice weekly until a 30 French sound could be easily passed. Following this the granulations and papillary tissue were destroyed by fulguration. Since then the patient has been relieved and has had no febrile attacks.

Mrs. L. A. J., aged 45, white, first examined June 26, 1939 complained of a constant sense of discomfort in the region o the bladder and urethra. She described this as feeling as i one had a "raw sore throat." There were no symptoms o bladder irritation. Several years before the patient had a pelvic operation to get relief from this pain, but it did not help. A year ago she passed some bloody urine on one occasion and following this had a severe lumbosacral backache for several days. Complete urologic study was negative except for pronounced chronic posterior urethritis. The urethra was dilated, and following this the granular and papillary masses in the urethral mucosa were fulgurated on four occasions. She has experienced complete relief from her pain and has remained well since then.

Mrs. D. G., aged 37, white, examined July 16, 1942, complained of pain generalized over the lumbar area for the past ten years; at times this would be severe enough to keep her in bed two or three days. She thought at times that the backache would be relieved somewhat by voiding. Also for ten years she had increased frequency of voiding during the day, nocturia two to five times and slight dysuria. On several occasions examinations revealed pus in the urine, and irrigations of the kidney pelves were carried out. She would always experience relief from her backache and urinary symptoms for about a week following this. At no time has she had any spells of high fever. Urinalysis showed 8 to 10 pus cells per high power field; there was a tight urethral stricture and a chronic urethritis; there was slight congestion of the trigone. The remainder of the bladder was normal. Urine from each kidney was free of pus, and pyeloureterograms were normal. Dilation of the urethral stricture and fulguration of the urethral mucosa twice at two month intervals cured the condition.

Mrs. J. D. E., aged 30, white, for several years suffered from constant lumbar backache and nervous and mild attacks of urinary frequency. In August 1941 she had a suspension of her uterus and partial removal of one ovary. She had to be catheterized several times afterward, and following this she was bothered a great deal with frequency of urination in the daytime, mild dysuria and a lack of sense of relief after voiding. At the time of our examination in January 1942 she still had the original backache and was extremely nervous. Urinalysis was negative. There was a pronounced chronic posterior urethritis. The urethra had been widely dilated without relieving her symptoms. Fulguration of the granular and papillary masses in the urethra on two occasions relieved her completely of backache, bladder symptoms and nervousness.

Mrs. W. F. J., aged 35, examined May 11, 1941, had suffered for seven years from frequency, dysuria and at times difficulty in voiding. Two years after the onset of these symptoms hysterectomy was performed to relieve "pressure on the bladder," but this did not give any relief. About one year ago the patient developed burning pain in the right hypochondrium, right loin and right lumbosacral area. Urinalysis was negative except for an occasional white blood cell. Complete urologic study revealed a stricture of the urethra and a chronic granular and papillary urethritis. Following dilation of the urethra to 30 French caliber and fulguration of the granular and papillary areas in the urethra mucosa the patient was completely relieved of her pain and her urinary symptoms and has not had any recurrence of trouble since then.

Mrs. C. G. H., aged 32, seen first in June 1940, complained of a severe pain in the right loin, beginning in the costovertebral angle and radiating along the ureter. At times she required hypodermic injections for relief. She also had frequent attacks of bladder irritation (frequency and burning). These symptoms had been present for eight years. She had had one pelvic operation with no relief, and one of the best urologists in our part of the country had done a nephropexy. This also failed to give her any relief in spite of the fact that our pyelogram in the erect position showed that the kidney was normal and well up in position. Our examination showed a moderate tightness of the urethra and a normal bladder, but a pronounced papillary posterior urethritis. Dilation and fulguration relieved her not only of the bladder irritation but of the pain in the right loin.

Mrs. M. C., aged 43, seen April 3, 1944, fourteen years ago, following delivery, began to have pain in the right loin, the right iliac region and the inner side of the right thigh. She began also to have a bladder frequency and burning. These symptoms had persisted in spite of several operations for their relief. A suspension was done, at which time the appendix was removed. Then the right tube and ovary were removed. Then a hysterectomy was done. Next a plastic operation on the right ureteropelvic junction was done, and finally the right kidney was removed. But in spite of all these various operations she continued to suffer from bladder irritation and the aforementioned pains. The first observation made on cystoscopy was that she had a grossly trabeculated bladder. She was then asked about difficulty in voiding, which she said had been present for the past four years. Otherwise the bladder was normal. There was a pronounced collarette surrounding the internal urethral orifice and also some papillary masses and granulation tissue. She had suffered so long and had had so many operations without relief that we decided to do a transurethral resection of the entire pathologic area in the region of the internal urethral orifice. This was done March 4, 1944. Following this she was relieved within twenty-four hours not only of her bladder irritation but also of the pain in the right loin, iliac region and inner side of the thigh. In our wildest enthusiasm we had not hoped for such an immediate and complete relief. But we have had a report from her doctor and she is still relieved.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. HEANEY AND KRETSCHMER AND DRS. FOLSOM AND O'BRIEN

DR. VINCENT J. O'CONOR, Chicago: Obstructive lesions at the neck of the bladder in women are confusing from the point of view of interpretation. I have the material of 19 transurethral sections of the female bladder neck, individuals studied carefully with urinary obstruction, not the simple type with multiple polyps of the posterior urethra and vesical neck which we all see so frequently but individuals with actual retention of urine not due to mechanical causes from a relaxed bladder. A study of this material shows that the character of the tissue varies from pure muscular tissue, pure fibrotic tissue, to mixed glandular elements and in some instances hyperplasia and inflammatory tissue, so that it is a waste of time to argue about the exact nature of the obstructing tissue at the bladder neck in women. Many of these women who have frequent dysuria, difficulty in urinating and perhaps recurrent attacks of upper urinary infection, which are probably precipitated by the urethral lesion, can be benefited by relieving the mechanical obstruction at the bladder neck, providing for free urination, and restoration of complete bladder emptying. This operation is one, of course, which we enter rather with trepidation because of the small amount of tissue one can remove without running the danger of making the patient incontinent.

DR. V. D. LESPINASSE, Chicago: A woman of this type was catheterized with the ordinary metal female catheter. Everything was strictly orthodox up to the point of removing the catheter. The catheter was about half removed when it stuck, and it reminded me of an experience I had some twenty-five years ago when a rat tail catheter coiled up in the bladder; in this situation we had no long catheter to tie into a knot, so after deliberating a short time I decided to put traction on the catheter. This I did and suddenly it came away with a few drops of blood. In the eye of the catheter, firmly wedged, was a urethral polyp of the kind under discussion. Immediate cystoscopy revealed clearly the source of this hemorrhage just at the urethrovesical junction. So, as the urine was flowing into the catheter, the little polyp went through the eye with it and was caught and torn off when the catheter was removed.

DR. JOHN ORMOND, Detroit: In my experience a great many of these women who come in with these urinary symptoms are not improved by treatment to the urethra alone. We have to consider the trigone, which seems to be a frequent source of infection to the urethra. The procedure that I have been using may not be new. I haven't seen it described. It is merely to take the retrospective cystoscope that comes with the resectoscope, fill the bladder with water, insert the retrospective cystoscope and examine the orifice from the inside.

DR. H. W. HOWARD, Portland, Ore.: The admitted infection of the paraurethral glands may have a lymphatic drainage from the focus to the pelvis and thus account for the remote conveyance of symptoms, as Drs. Folsom and O'Brien have mentioned, into the hip and the inside of the thigh. The ordinary tissue in the suprapubic space is lacy and pink and allows free movement of all the organs contained, but as lymphangitis develops there the tissue takes on a firmer and a whiter appearance. It seems clear that certain irregularities in the ureters which had been noticed in well made urethral glands in the pelvic level otherwise not accounted for were now accounted for on the basis of lymphangitis because of scarring of these areas, with constriction and deformity on the urethra. When the wall of the pelvis is palpated as far as the finger can reach, using the rectum as a means of approach, the wall of the pelvis is tender throughout. One easily palpates the sides, which under these circumstances are tender. Likewise the trigone is tender at the point of which the tenderness is at the junction of the trigone and urethra with these glands which are presumed to be most abundant.

LIEUTENANT COLONEL HARRY KIRSCHBAUM, M. C., A. U. S.: The gynecologist who is interested in urology of course recognizes these conditions, but the gynecologist has a difficult time convincing the urologist that they exist. There are, however, many cases showing these findings and no symptoms. Of course, having gynecologic patients—20 per cent of them have a frequency in urination—I feel that it is a gynecologist's duty to be thoroughly familiar with the female bladder. I want to ask Drs. Folsom and O'Brien what their percentage of cures was as far as they have noticed in connection with cauterization of the cervix for endocervicitis. If a patient with endocervicitis is cured, will the urethral symptoms clear up spontaneously or will they require further urethral treatment?

DR. H. L. KRETSCHMER, Chicago: Dr. Heaney and I have been impressed for a long time with the fact that we see so few cases at the Presbyterian Hospital. I gained the impression in talking with urologists in various sections of the country that they see many more cases than we do. This led to a study of the cases of pyelitis of pregnancy that occurred in the hospital for the past ten years. The results of our study form the basis of our paper. We believe that the number of cases that occur in any large clinic or hospital is in direct ratio to the care and attention given to the removal of foci of infection during the antepartum period. I agree with Drs. Folsom and O'Brien that the female urethra is frequently the seat of chronic infection and that this in turn is responsible for the patients' symptoms. Unfortunately this fact is overlooked. Besides chronic urethritis may I call attention to infection in the paraurethral and periurethral glands as a frequent cause of the symptoms. The diagnosis is relatively simple if we only bear them in mind.

DR. A. I. FOLSOM, Dallas, Texas: In my experience the caruncle has been greatly exaggerated. In the majority of instances that I have seen, these women who have had caruncles burned off and excised still have their trouble and we find the real cause of it in the posterior urethra. Dr. Kretschmer emphasizes that he sees many of these cases that do not show any symptoms and, of course, that is entirely true, and I have no explanation for it. Dr. Ormond says that some of these

persistent cases that do not respond to ordinary treatment show a definite trigonitis. The interesting thing to me about trigonitis is that it has been considered a clinical entity, whereas it is not a clinical entity at all. It is simply an extension of this inflammatory lesion in the posterior urethra on to the trigone. I have seen actual leukoplakia extending down from the urethral orifice and over the trigone and I have had to use fulguration to get relief. The cervix is definitely connected with the urethra and in many of these resistant cases there is a chronic endocervicitis; clearing that up will help the patient materially. This is not always true because there is not always this connection, but in a persistently resistant case one should never overlook the possibility of there being also an infection in the cervix.

INSULIN MIXTURES IN THE TREATMENT OF DIABETES

VARIABLE VERSUS FIXED RATIOS OF INSULIN AND PROTAMINE ZINC INSULIN

DAVID ADLERSBERG, M.D.
AND
HENRY DOLGER, M.D.
NEW YORK

The introduction of protamine insulin by Hagedorn and his co-workers [1] in 1935 represented a milestone in the development of insulin therapy in diabetes. The result of extensive efforts to prolong the action of insulin, it simplified treatment in many ways. Multiple injections, even in severe cases, were reduced to one injection, glycosuria and ketosis were better controlled and hypoglycemic shocks occurred less frequently. Despite the enthusiastic reception of the new insulin preparation, many authors in Europe and America [2] called attention to disadvantages caused by insolubility and slow rate of absorption of protamine insulin. In some, particularly in severe cases, the difficulties encountered were excessive glycosuria after meals and hypoglycemic reactions occurring at night and in the morning. Raising the dose to reduce the postprandial glycosuria provoked early morning shocks, while reducing the dose to avoid repeated reactions aggravated the diurnal glycosuria.

The limitations inherent in the product were increased by two further developments: 1. The addition of zinc to protamine insulin improved its stability but led to further prolongation of action.[3] The general trend toward higher carbohydrate diets [4] intensified diurnal glycosuria, particularly in severe diabetes.

The difficulties encountered in the practical use of protamine zinc insulin produced two reactions among clinicians. One group relaxed the standards of control considerably in severe cases and tolerated philosophically even pronounced glycosuria as long as ketosis, loss of weight, increased thirst and polyuria were absent.[5] The other group, adhering to more rigid standards of control, attempted to circumvent the limitations of insoluble insulin by various devices. Attempts were made to adapt the diet to the mode of action of protamine zinc insulin by altering the distribution or the carbohydrate and protein composition of meals, by extra feedings before retiring, and similar procedures.[6] Others tried to modify the action of protamine zinc insulin by giving it in two injections a day or by supplementing it with a separate dose of regular insulin.[7] Mixing soluble and insoluble insulin was considered at that time incompatible, and various stratagems were devised to separate them in the syringe, such as "layering" the insulin or the use of a double barreled syringe.[8] Later the practicability of mixing the two insulins in a vial or in the syringe was accepted.

It is interesting to note that the first effort to correct the slow action of protamine insulin was made by Krarup.[9] His experience with "insulin 341" revealed both quick effect and long duration. Protamine zinc insulin contains an excess of protamine, which precipitates part of added soluble insulin. By using varying proportions of soluble and insoluble insulin, various degrees of immediate and prolonged activity can be achieved. The prompt effect of mixtures depends on the amount and ratio of the two components, the excess of protamine present and the resultant p_H. These factors have been fully discussed in many publications.[10] Peck's [11] studies finally proved that in buffered mixtures of soluble and insoluble insulin the prompt effect runs parallel to the proportion of regular and the delayed effect to the proportion of protamine zinc insulin: e. g., a mixture of regular and protamine zinc insulin in the ratio 1 : 3 contained approximately 10 per cent rapidly acting insulin, a 1 : 1 mixture 25 per cent and a 3 : 1 mixture 65 per cent.

While most clinicians employed various types of mixtures, others advocated fixed ratios of soluble and insoluble insulin. The arguments [12] in favor of a uniform mixture were standardization of therapy and simplification of procedure by the use of only one

insulin mixture in all cases, avoidance of inaccuracy of measurement and of confusion "created by the use of two preparations with different properties."

Table 1 lists the insulin mixtures proposed. It is evident that the ratios vary considerably. Satisfactory results were apparently achieved with ratios of soluble and insoluble insulin varying from 3 : 1 to 1 : 3.

ANALYSIS OF CLINICAL MATERIAL

This report presents a study of 1,131 patients from the diabetes clinic of a large general hospital. The group includes all types of diabetes above the age of 14. As indicated in table 2, 46 per cent were mild cases of diabetes treated with diet alone without insulin; 54 per cent required insulin. Of the 611 patients treated with insulin only 15 (2.5 per cent) have been using two injections a day and only 1 used three injections; 596 patients (97.5 per cent) received but one daily injection.

Efficacy of Protamine Zinc Insulin Alone.—Of the insulin group 484 patients (79 per cent) were managed satisfactorily with one daily injection of protamine zinc insulin. The daily doses varied from 6 to 200 units

TABLE 2.—*Analysis of Clinical Material*

	Number	Per Cent
Diet alone, no insulin	520	46
Insulin treated	611	54
Total number of cases	1,131	100

	80	13
	30	5
[illegible] insulin	17	3
Total number of cases	611	100

(chart 1). Almost half the patients received 5 to 20 units, one third 25 to 40 units, one eighth 45 to 60 units and only one twelfth 65 to 80 units. In other words, 77 per cent received 40 units or less.

The results of one daily injection of protamine zinc insulin were very satisfactory. This insulin was of particular advantage in the great mass of mild and moderately severe cases. But even in severe diabetes good results could often be obtained. Sixty-four patients were satisfactorily controlled with 45 to 60 units and 35 patients with 65 to 80 units.

It was the practice in the clinic to begin treatment with protamine zinc insulin solely whenever the diabetes could not be controlled by diet alone. The dose was gradually increased until normal fasting blood sugar levels were approximated and postprandial glycosuria absent or reduced to moderate amounts (0.5 to 1 per cent). In about one eighth of the cases this result could not be achieved. It was impossible to increase the dose of protamine zinc insulin in the presence of nocturnal hypoglycemic reactions or a normal or subnormal fasting blood sugar level. The pronounced diurnal glycosuria in these cases necessitated the use of regular insulin in a mixture.

On the other hand the diabetes of a few patients was better controlled with protamine zinc insulin alone than with mixtures. Frequent diurnal hypoglycemic reactions were precipitated by the prompt effect of the regular insulin. This occurred in a few insulin sensitive patients who because of strenuous physical work or irregular delayed mealtimes had hypoglycemic reactions on mixtures containing [illegible] small amounts of regular insulin. The [illegible] amounts of regular insulin is usually tantamount to increasing the total dose of protamine zinc insulin. However, the following case illustrates the daytime shocks caused by small doses of regular insulin in the mixture:

CASE 1.—A woman aged 47 who had had diabetes for over two years had been taking a mixture of 15 units regular plus 35 units protamine zinc insulin in one injection before breakfast

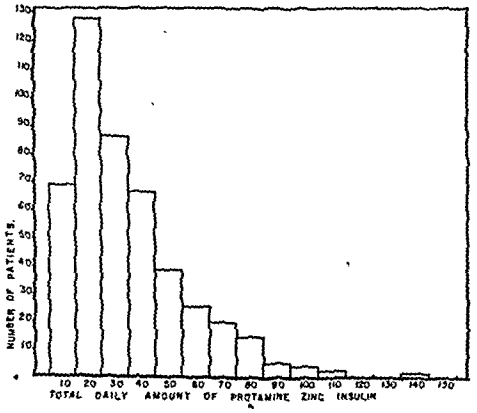

Chart 1.—Doses of protamine zinc insulin used by 484 patients.

at the suggestion of another physician. This provoked many severe shocks around noon, requiring hospitalization on two occasions. Because of the frequent reactions in the presence of a practically normal fasting blood sugar level, regular insulin was discontinued and the patient was given 40 units of protamine zinc insulin alone. Since then she has remained entirely free from hypoglycemic shocks and has been well controlled.

The diets prescribed for patients taking all types of insulin ranged from 150 to 250 Gm. of carbohydrate, 60 to 80 Gm. of protein and 60 to 100 Gm. of fat, with the accepted variations depending on age, sex, nutritional status and occupation. One group of 50 patients has been maintained on an unlimited carbohydrate intake (up to 500 Gm.) for a special study. Eight of this group are represented in chart 1 as taking over 90 units of protamine zinc insulin. These were most severe cases of diabetes observed over a long period of time who because of persistent glycosuria were therapeutic problems under any diet-insulin regimen attempted heretofore. Others of this group were more satisfactorily controlled on mixtures of regular and protamine zinc insulin.

Mixtures of Regular and Protamine Zinc Insulin.—As early as 1938 the difficulty in controlling some patients of the Diabetes Clinic of the Mount Sinai Hospital with one injection of protamine zinc insulin led to the additional use of small amounts of regular insulin. At first the two types were administered in separate injections. As the possibility of mixing the two in the syringe became practicable, several types of mixtures were used. Starting with 5 to 15 units of regular insulin added to two to five times as much protamine zinc insulin, it soon became evident that the proportion of regular insulin had to be increased to achieve the desired double action of the mixture. In the course of time equal proportions of the two types of insulin were frequently used and not infrequently the regular exceeded the protamine zinc insulin in the mixtures.

For practical purposes no difference exists between regular and crystalline zinc insulin in mixtures, and the term regular in this paper is applied to both types. Fifty-six per cent of the patients treated with mixtures used crystalline zinc insulin and 44 per cent regular insulin. The mixtures were prepared by the patients directly in the syringe, immediately before injection; no stock solutions of fixed proportions were used. The patients followed the accepted technic in taking the regular insulin into the syringe first to avoid beclouding

TABLE 3.—*Grouping of Patients According to Total Dose of Insulin Mixtures*

Total Units of Insulin Used in Mixtures	Number of Cases	Per Cent
10 - 20	5	6.25
25 - 40	19	23.75
45 - 60	18	22.50
65 - 80	19	23.75
85 - 100	15	18.75
105 - 200	4	5.0
	80	100.0

the regular insulin by possible admixture with protamine. The same strengths were used for the two types of insulin to avoid confusion; that is, no mixtures of U 40 with U 80 were permitted. Under these circumstances no confusion or difficulties were encountered in the preparation of the mixtures.

Whenever a patient could not be controlled on protamine zinc insulin alone without either nocturnal hypoglycemic reactions and/or considerable diurnal glycosuria, mixtures were indicated. At first the total dose of insulin was not changed but one fourth or one third of it was given as regular insulin. Guided by the fasting blood sugar level and the daily fractional urine specimens subsequent alterations were made in the dosage of regular or protamine zinc insulin or both. If the fasting blood sugar level remained within acceptable limits (100 to 150 mg. per hundred cubic centimeters) yet diurnal glycosuria persisted, the proportion of regular insulin was progressively increased while the dose of protamine zinc insulin remained unchanged or was proportionately reduced; the original ratio of 1:3 or 1:2 thus became 1:1 or even greater with respect to the regular insulin. If substitution of regular insulin for a part of the original dose of protamine zinc insulin led to elevation of the fasting blood sugar level in the absence of diurnal glycosuria, an increase in the amount of protamine zinc insulin was indicated. On the other hand, nocturnal hypoglycemic reactions or subnormal fasting blood sugar levels without manifest hypoglycemic symptoms necessitated reduction of the protamine zinc insulin fraction. The daily insulin requirement was often lessened with the use of mixtures. In insulin sensitive patients especially it proved advisable to reduce the total dose by 20 to 30 per cent when changing to mixtures. Under continued observation of both fasting blood sugar level and fractional urine specimens the optimal ratio and

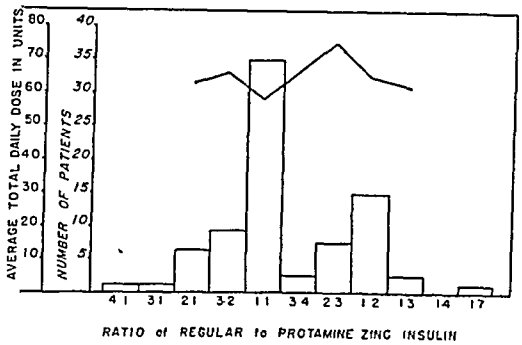

Chart 2.—Distribution of the ratios and total amounts of regular and protamine zinc insulin used by 80 patients. The columns present the number of cases on each ratio, the upper curve the average total dose of insulin.

dose of regular and protamine zinc insulin were established for each individual. Since the full effect of protamine zinc insulin and mixtures is not obtained in the first twenty-four hours, evaluation of the final action of any mixture requires observation for at least three to four days and longer. Conclusions based on one day studies are not reliable.

For convenience, mixture of the same amount of regular and protamine zinc insulin was termed "equal" mixture, while the term "surplus regular" mixture applied to one containing over 50 per cent regular insulin, and the term "surplus protamine" mixture to one containing less than 50 per cent regular insulin.

Eighty patients, or 13 per cent, of those treated with insulin, have been receiving mixtures. Chart 2 presents the distribution of the various ratios and the daily amounts of insulin. It appears that 75 patients (94 per cent) have been on ratios of regular to protamine zinc insulin ranging from 2:1 to 1:2, while the wider ratios were used by only 5 patients. Thirty-five (44 per cent) were maintained on "equal" mixtures. Seventeen (21 per cent) were maintained on "surplus regular" mixtures (ratios 4:1, 3:1, 2:1, 3:2); 28 (35 per cent) were taking "surplus protamine" mixtures (ratios 3:4, 2:3, 1:2, 1:3, 1:4, 1:7), as shown in chart 3. Although the tendency in the past few years has been to increase the proportion of regular insulin in the mixture, it is of interest to note that one third of the patients were still satisfactorily controlled on mixtures containing less than 50 per cent of regular insulin, while only one fifth of the patients required proportions of regular insulin of over 50 per cent.

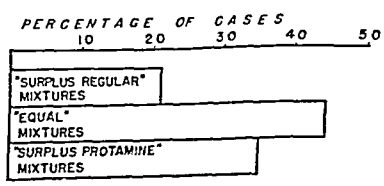

Chart 3.—Relative distribution of the three types of mixtures.

The total amount of insulin used daily in the mixtures varied widely from 10 to 200 units. Table 3 groups the patients according to the dose. Only 24 used 10 to 40 units daily, while 56 required over 45 units, indicating that this series contains a greater proportion of cases of severe diabetes. The relationship between the average total dose and the ratio of regular to protamine zinc insulin is presented in the upper curve

of chart 2. The lowest daily total dose was found in the "equal" mixture group (average 59 units), the highest in the group on ratio 2:3 (average 76 units). The average daily dose of mixtures for all patients was 64.6 units. It should be noted that practically the same total dose of the mixtures prevailed with widely different ratios. In other words, depending on the individual needs of the patients, similar doses of insulin mixtures have been used with "equal," "surplus regular" and "surplus protamine" mixtures.

The following cases illustrate the technic of flexible adjustment of insulin ratios to the individual requirements of patients. These patients were purposefully selected from the group because of the severity of the diabetes and the difficulties in management prior to the institution of mixtures. No alterations in the diet were made during these studies.

CASE 2.—A woman aged 66 with diabetes for twenty-one years presented considerable difficulties in management because of shocks, severe hyperglycemia and glycosuria. She required over 100 units of regular insulin at first and later the same amount of protamine zinc insulin. For the past two years she took 30 units of regular and 60 units of protamine zinc insulin in two separate injections. The fasting blood sugar values were persistently over 250 mg. per hundred cubic centimeters with daily glycosuria of 2 to 5 per cent and occasional nocturnal hypoglycemic reactions. The administration of the two types of insulin in the same dosage as a mixture in one syringe had no striking effect. Definite improvement, however, followed the use of a different ratio (45-45), leaving the total dose unchanged. Fasting blood sugar levels dropped to around 160 mg. per hundred cubic centimeters and fractional urine specimens ranged from 0 to 1 per cent. Much subjective improvement was noted. See table 4, case 2, for day profile.

CASE 3.—A girl aged 17 years with diabetes for eight years had been taking 20 units of regular and 60 units of protamine zinc insulin in two separate injections for the past three years. On this regimen the fasting blood sugar levels were over 200 mg. per hundred cubic centimeters and considerable glycosuria was present. One daily injection of a mixture containing the former unitage of regular and protamine zinc insulin effected better control of the glycosuria. The total dose was gradually reduced to 20 units of regular and 44 units of protamine zinc insulin. Fasting blood sugar levels ranged between 98 and 133 mg. per hundred cubic centimeters and the daily glycosuria from 0 to 1 per cent.

CASE 4.—A man aged 48 with diabetes for ten years developed frequent morning shocks when changed from 40 units of regular insulin given in two equal injections to an identical dose of protamine zinc insulin in one injection. To overcome this difficulty he was placed on a mixture of 10 units of regular and 20 units of protamine zinc insulin (1:2) but developed considerable glycosuria and thirst in the afternoon and evening. The ratio was then reversed to 20 units of regular and 10 units of protamine zinc insulin (2:1) to counteract the glycosuria, but severe hypoglycemic reactions occurred at noon. At present with one daily injection of 10 units of regular and 23 units of protamine zinc insulin in a mixture he is satisfactorily controlled without shocks. Fasting blood sugar levels ranged from 100 to 145 mg. per hundred cubic centimeters and fractional urine specimens were negative for sugar. See table 4, case 4, for day profile.

CASE 5.—A woman aged 24 with diabetes for fifteen years had uncontrollable glycosuria and loss of weight despite the use of 84 units of protamine zinc insulin. Mixtures of regular and protamine zinc insulin with ratios of 20:60, 30:60 and 40:40 (1:3, 1:2 and 1:1) were given over a two year period with unsatisfactory results owing to persistent glycosuria and inability to gain weight. Finally a mixture of 60:30 (2:1) effected good control of the diabetes with subsequent gain of 10 pounds (4.5 Kg.) in weight. The fasting blood sugar levels ranged from 120 to 136 mg. per hundred cubic centimeters, and fractional urine specimens were sugar free. See table 4, case 5, for day profile.

CASE 6.—A woman aged 50 with diabetes for eighteen years had been taking 90 to 120 units daily of regular or protamine zinc insulin with fasting blood sugar levels of 300 mg. per hundred cubic centimeters and fractional urine specimens of 3.3 to 5 per cent. A change to an equal mixture of 50 units of regular and 50 units of protamine zinc insulin had an excellent effect. Fasting blood sugar levels ranged now from 172 to 200 mg. per hundred cubic centimeters and fractional urine specimens from 0 to 1 per cent. She has gained 9 pounds (4.1 Kg.) in weight. See table 4, case 6, for day profile.

The striking decrease in the daily insulin requirement seen not infrequently is illustrated by the following cases, in which only the insulin dosage and ratio were altered while the diets remained unchanged:

CASE 7.—A man aged 44 with diabetes for eleven years took 80 units of regular insulin twice daily (total 160 units) for *many* years. His fasting blood sugar levels ranged around 200 mg. per hundred cubic centimeters, and considerable glycosuria was present before dinner. With the administration of mixtures, satisfactory control was achieved with a total dose of 90 units consisting of 30 units of regular plus 60 units of protamine zinc insulin (1:2). Fasting blood sugar levels varied from 120 to 167 mg. per hundred cubic centimeters, and fractional urine specimens contained 0 to 0.6 per cent of sugar.

CASE 8.—A man aged 32 with diabetes for four years had been taking 120 units of protamine zinc insulin when he developed repeated hypoglycemic reactions. Progressive reduction of the dose to 80 units led to disappearance of the shocks but provoked severe glycosuria. An "equal" mixture of 60 units of regular and 60 units of protamine zinc insulin (total 120 units) controlled both difficulties. In the course of time reduction to 36 units of regular and 36 units of protamine zinc insulin (total 72 units) was possible. Fasting blood sugar levels ranged from 100 to 116 mg. per hundred cubic centimeters with no sugar in the fractional urine specimens. See table 4, case 7, for day profile.

These 7 patients typify the group with severe diabetes in whom the use of insulin mixtures represents a definite advance. The comparative ease with which mild and moderately severe cases of diabetes have been controlled by protamine zinc insulin alone made the use of mixtures for this group unnecessary as a rule.

TABLE 4.—*"Day Profiles" of Glycemia and Glycosuria of Seven Cases of Severe Diabetes Treated with Different Mixtures of Regular and Protamine Zinc Insulin*

Case	Total Dose of Mixture	Units Regular Insulin	Units Protamine Zinc Insulin	Ratio	Blood Sugar, Mg. per 100 Cc.				Urine Sugar, Gm. per 100 Cc.			
					8 A. M.	12 N.	4 P. M.	8 P. M.	8 A. M.	12 N.	4 P. M.	8 P. M.
1	80	20	60	1:3	160	198	166	184	0	0.5	0	0.5

7	72	36	36	1:1	116	195	152	152	0	0	0	0

In the clinic of the Mount Sinai Hospital the use of mixtures was reserved generally for patients with severe diabetes and the "problem" cases. The total dose in this group of patients is higher than that reported by other clinics using insulin mixtures for milder cases of diabetes.[13] Consequently, in evaluating the therapeutic results in the patients presented in this paper the difference in severity of the disease should be considered. In our opinion the use of mixtures led to better control of the diabetes by eliminating diurnal glycosuria, decreasing the frequency of hypoglycemic reactions, reducing the total dose of insulin required, making it possible for even the severely diabetic patient to use but a single daily injection. The administration of mixtures permits a greater flexibility and individualization of therapy than one daily injection of any other type of insulin alone. The degree of control possible with large doses of insulin in severe diabetes when different ratios are used is demonstrated in table 4. It presents the "day profiles" of blood sugar levels and glycosuria of 7 severely diabetic patients, some of whose histories have been given.

Globin Insulin.—Seventeen patients (2.8 per cent of all insulin cases) have been treated with one daily injection of globin insulin. The daily dose varied from 10 to 60 units, the average being 30 units. The group is too small to permit any conclusions.

Indications for Regular Insulin Alone.—Thirty patients (5 per cent of those requiring insulin) were controlled on regular insulin alone. Eighteen have been using one injection, 11 two injections and only 1 three injections daily. The average mild case was controlled with 10 to 20 units, while moderately severe cases received 30 to 40 units in two injections. Only 1 patient had 60 and 1 had 75 units.

Despite the satisfactory results with protamine zinc insulin and mixtures there still remains a group best controlled with one or two injections of regular insulin.[14] A few patients presented severe local irritation from protamine zinc and globin insulin, which in contrast to the usual experience did not subside with continued use. These patients preferred regular insulin even if two injections were required. A small group favored the use of regular insulin because of peculiarities of their occupation, such as frequent changes from day to night shifts. There is no reason to force these patients who have been doing well on one to two injections of regular insulin to change to other types of insulin.

Regular insulin remains the preparation of choice for the treatment of complications and emergencies of diabetes: infections, cardiac failure, angina pectoris and coronary occlusion, cerebral accidents, preoperative and postoperative treatment, and so on. Whenever maximum flexibility of therapy and avoidance of complicating hypoglycemia of even mild degree are imperative, as in angina pectoris, regular or crystalline insulin is preferable because of the prompt and short action.

COMMENT

Review of 1,131 diabetic patients of a large general hospital revealed several salient points. Approximately half were controlled by diet alone without insulin; the rest required insulin. Seventy-nine per cent of the latter group were maintained satisfactorily with protamine zinc insulin alone. This compares with the experience of other large clinics as follows: Joslin[15] 90 per cent, Peck[16] 75 per cent and John[17] 53 per cent and proves the value of protamine zinc insulin alone in controlling the vast majority of insulin treated diabetic patients. This group consists of mild, moderately severe and to a certain extent even the severe forms of the disease. It was in the latter group that mixtures of regular and protamine zinc insulin were employed with many advantages. Difficulties in management of this group with protamine zinc insulin alone led either to neglect of a considerable glycosuria or necessitated the administration of additional injections in the course of the day when the usual conservative standards of control were applied. Mixtures of insulin providing both the prompt effect of regular and the protracted effect of protamine zinc insulin helped to overcome these problems.

Eighty patients (13 per cent of those taking insulin) were maintained with various insulin mixtures, the average daily dose being 64.6 units. The results were in accord with those of Lawrence, the first to report the use of mixtures, and others. It was possible to control severe diabetes with a single daily injection of a mixture, maintain an acceptable blood sugar level, reduce glycosuria to minimal quantities and prevent disturbing hypoglycemic reactions. This was accomplished with diets containing liberal ratios of carbohydrate, protein and fat.

Devious dietary stratagems formerly proposed to overcome the limitations of protamine zinc insulin should be avoided usually since they impose unnatural restrictions (such as frequent feedings, limited carbohydrate intake for breakfast or high protein feeding on retiring). One of the aims of modern diabetic therapy should be close approximation to a normal life for the patient, especially with regard to the composition of food and the distribution and time of meals. Mixtures of insulin enable the physician to adapt the insulin-diet regimen to the individual instead of molding the patient to fit the peculiarities of any special diet or type of insulin. The wide flexibility of the ratios in variable mixtures fulfils the individual requirements of therapy in severe and "problem" cases of diabetes. The increasing importance of mixtures is indicated by the fact that the Food and Drug Administration has conducted a survey on this subject.

Initially small ratios of regular insulin in the mixtures were employed in the clinic. In the course of time the advantage of higher proportions of regular insulin became apparent. The procedure employed in arriving at the optimal ratio for each patient has been discussed. Selection of the ultimate ratio for each patient followed prolonged trial with less effective ratios.

Of the 80 patients using mixtures, almost one half have been employing "equal" mixtures (1:1), one fifth "surplus regular" mixtures and one third "surplus protamine" mixtures. While the general trend has been to increase the proportions of regular insulin in mixtures to 50 per cent or more, it is noteworthy that one third of the patients were satisfactorily controlled on mixtures containing less than 50 per cent of regular insulin. In vitro, small doses of regular insulin in

mixtures with larger amounts of protamine zinc insulin are immediately precipitated by the excess protamine, thereby increasing the dose of protamine zinc insulin by the amount of regular insulin added. No rapid insulin action could therefore be expected. Clinical experience is at variance with the results obtained in vitro. Our results with "surplus protamine" mixtures revealed definite prompt insulin effects not obtained with [illegible] of protamine zinc insulin alone. [illegible] with reports by Lawrence,[18] Peck[11] and Sparks and John.[17] The discrepancy between the results in vitro and in vivo may be explained by the increased solubility of the mixture resulting in a more rapid release of insulin in the tissues.

What is the advantage of variable insulin mixtures compared with fixed preparations? Contrary to the proponents of stock mixtures with fixed proportions, no technical difficulties in the preparation of mixtures by the patients were encountered in the clinic, nor were inaccuracies in measurements a problem. Simple demonstration of the technic of administration and the use of the same strengths for the two types of insulin precluded any confusion. Constant employment of the same brand of insulin prevented any error possible by variation of the excess protamine in different makes. Although the use of a single mixture would simplify the treatment of diabetes, there is at present no agreement as to the ideal ratio (table 1). Our experience indicates the impracticability of one stock mixture of fixed proportion. The use of a single fixed ratio at times requires individualization "by means of adjustment of the diet and frequency and dosage of injection,"[19] thereby negating the principle of simplified therapy. It must be appreciated that "patients are different and require insulins having different time activities."[16] Variability of ratios provides for flexible and individual treatment in a "tailor-made" fashion. The introduction of one or more stock mixtures is not recommended at present, but future investigations may effect a change in this opinion. We agree fully with the statement by Joslin[20] that "the fewer the types of insulin for sale, the less confused will patients be."

SUMMARY

1. A review of 1,131 diabetic patients of a large general hospital revealed that 46 per cent were controlled with diet alone, while 54 per cent required insulin.

2. In the insulin group 79 per cent were satisfactorily maintained by one daily injection of protamine zinc insulin, 5 per cent by one to three injections of regular insulin, 3 per cent by one injection of globin insulin and 13 per cent by mixtures of regular and protamine zinc insulin.

3. Of the 80 patients using mixtures, 44 per cent were on "equal" mixtures, 35 per cent on "surplus protamine" and 21 per cent on "surplus regular" mixtures. Mixtures present a decided advance in the treatment of severe diabetes.

4. The chief advantages of mixtures are flexibility and adaptability to the requirements of the individual. The use of a single stock mixture in fixed proportions for the treatment of diabetes is at present not recommended.

ABSTRACT OF DISCUSSION

DR. HOWARD F. ROOT, Boston: At present many doctors feel somewhat bewildered by the pressure applied in favor of one type of insulin or another. Patients may be taking, for various reasons, histone insulin, globin insulin, cloudy protamine insulin, clear protamine insulin which is pretty acid, crystalline insulin or regular insulin or, finally, mixtures of clear and protamine insulin varying in proportions from 1:1 to 6:1. Doctors might be pardoned for forgetting some important facts in dealing with such a variety of insulins. Since the proportions have varied from 1:3 to 6:1, Drs. Adlersberg and Dolger conclude that probably no one fixed mixture yet has been found which will suit all or even a large majority of patients. It is fine that they have found no difficulty in teaching patients to adjust the mixtures, particularly if the same strength, either 40 or 80 units, is used for the two insulins. Another point mentioned by the authors is important. With any insulin combination there will still be the occasional diabetic patient who is so sensitive not merely to insulin but to the effects of exercise, to changes in his own internal metabolism, that he will need individual adjustment of diet and occasionally supplementary insulin. At present, at the Deaconess Hospital in Boston, the number of patients on these various types of insulin is being reduced. We are trying to work toward simpler and fewer insulins. But this study gives us more confidence that soon, with the aid of the chemists, there will emerge one protamine zinc insulin with some rapid insulin in the mixture so that one can count on one protamine insulin and one other rapid insulin as the total armamentarium as far as insulin is concerned.

THIOURACIL IN THYROTOXICOSIS

OBSERVATIONS IN THE TREATMENT OF THIRTY-TWO PATIENTS

WILLIAM S. REVENO, M.D.

DETROIT

In the relatively short period of time since Astwood[1] first reported on the action of the thyroid inhibitors, thiourea and thiouracil, numerous reports, generally confirming the original observations, have appeared.[2] Most of the experience has been with thiouracil, and few instances of resistance to the drug have been recorded.[3] Unfavorable reactions[4] have been encoun-

From the Department of Medicine, Harper Hospital and Wayne University College of Medicine.

Thiouracil was supplied by Dr. Stanton M. Hardy of the Lederle Laboratories, Inc., Pearl River, N. Y.

tered in approximately 10 per cent of those treated, the most alarming disturbance being agranulocytosis. Despite this obstacle, investigations are continuing and a sizable and revealing clinical experience is gradually being acquired.

In an earlier report in THE JOURNAL I [5] described the treatment of 9 patients, of whom 6 were improved, 2 stopped treatment too early and 1 failed to respond. The present report deals with a broader series of observations made in the treatment of 32 patients. Fifteen of these, 11 females and 4 males, ranging in age from 16 to 66, had toxic diffuse goiters. Seventeen, 12 women and 5 men, aged 39 to 82, had toxic nodular goiters. Symptoms had been present for from two months to fifteen years in the first group and from two weeks to twenty years in the second. Twenty of the total had iodine up to the beginning of treatment with thiouracil, and 2 of these (both with toxic diffuse goiters) had x-ray therapy in addition. Five had had surgery for toxic diffuse goiter, 1 of these having had two thyroidectomies. The average initial basal metabolism was plus 32 per cent in those with toxic diffuse goiters and plus 22 per cent in those with the adenomatous type. All were ambulatory from the beginning of treatment except 3 hospitalized patients who soon were returned to general circulation.

INITIAL DOSAGE OF THIOURACIL

Thirteen of the patients (mostly those included in the first study) were started on 0.8 Gm. daily divided into four doses. The remainder were started on 0.6 Gm. divided into three doses. This appears to be an adequate starting dose for all ordinary purposes, particularly for patients not previously iodized. As soon as the rate of metabolism reached zero or a minus level, reduction was made to 0.4 Gm. daily divided into two doses. Further reduction to 0.1 Gm. twice daily was made as soon as the basal metabolic rate stabilized between plus 5 per cent and minus 10 per cent. Observations, including blood studies, were made every two weeks until stabilization and every four weeks thereafter. Blood cholesterol determinations have been discontinued, since they added little of value to the study.

CLINICAL IMPROVEMENT

In the patients with diffuse goiters, subjective improvement occurred earlier than in those with the adenomatous type. The average time in the former was a little over three weeks, with little difference existing because of previous iodization. In the latter the average time was over nine weeks, the longest interval occurring in those who had had iodine. Weight gain was noted in all patients.

NORMAL BASAL METABOLIC RATE

When the basal metabolism reached plus 5 or lower, it was considered that a normal level had been attained. Patients with diffuse goiters took from three to ten weeks to reach this point, previous iodization exerting little influence. In the second group, a normal level was reached anywhere from two weeks to thirteen months, the longest time being taken by those previously iodized.

Of special interest is the rise in the basal metabolic rate noted shortly after beginning thiouracil therapy, in those patients formerly taking iodine. This was noted in 5 instances and was first attributed to resistance to thiouracil. However, subsequent drop in the basal metabolic rate proved the initial rise to have been due to release from iodine influence coupled with a delay in appearance of thiouracil effect. Unless this is kept in mind, the drug may be discredited and its benefits denied some patients. It is therefore important to persist with the administration of thiouracil, particularly in those who have been previously iodized.

DURATION AND RESULTS OF TREATMENT

Nine patients have been under treatment longer than six months. All except 2 (both with toxic adenomas) have normal rates of metabolism and are symptom free. One of these 2 who failed to respond in expected fashion has now been under observation sixteen months and was first classed as a failure in the initial series of cases reported. The other had been satisfactorily controlled after five months' treatment and voluntarily stopped taking the drug. Within three weeks the former symptoms recurred, and there was rapid enlargement of the right lobe with an increase in the basal metabolic rate to plus 21 per cent. Thyroidectomy was successfully performed and the gland showed recent hemorrhage. Four months later the basal metabolic rate was plus 14 per cent without treatment of any kind. The patient has not returned for further observation.

Twenty-one patients observed less than six months are in remission. One of the remaining 2 has not been treated long enough to be classified finally, while the other has failed to return after an early favorable response. One patient in this group had a successful thyroidectomy after six weeks' treatment, having previously failed to respond to iodine.

Twenty-nine of the 32 patients have responded favorably, 2 have not been treated long enough, and only 1 has failed to respond.

FINAL MAINTENANCE DOSAGE AND EFFECT OF STOPPING THE DRUG

Out of 28 patients in remission, 1 (with tox adenoma) has been taking no thiouracil for the past tw months (after fourteen months' treatment); 1 (wit toxic adenoma) has had no thiouracil for five month (after ten months' treatment). The first patient i beginning to show some evidence of renewed activity while the second is holding steadfastly to her state o remission. One patient (with toxic adenoma), in remis sion after eleven months' treatment, showed a return o symptoms seven weeks after stopping thiouracil and i now controlled by 0.1 Gm. daily. One patient with recurrent hyperthyroidism (toxic diffuse), brought under control in eight weeks' time, was maintained on 0.2 Gm. daily for another eight weeks, at which time the drug was stopped. Within three days symptoms had returned and she is now back in remission on a maintenance dose of 0.4 Gm. daily. Still another patient with toxic diffuse goiter showed a return of symptoms seventeen days after stopping treatment and is back again in remission on 0.2 Gm. daily.

Of 5 patients (3 with toxic adenomas and 2 with toxic diffuse goiters) only 1 has remained in remission after stopping the drug. Three have relapsed and are back under control on small doses of thiouracil, while the fourth shows evidence of relapsing. From this small experience it is difficult to predict when and in whom the drug may be stopped. At this point it appears desirable to determine an individual minimum maintenance dose and to continue with this for an indeterminate period. The average maintenance dose ranges from 0.1 to 0.4 Gm. daily.

5. Reveno, W. S.: Thyrotoxicosis Treated with Thiouracil, J. A. M. A. 126: 153 (Sept. 16) 1944.

CHANGES IN THE THYROID GLAND

Under the influence of treatment, goiters tend to increase in size and become softer during the first few weeks. In the toxic diffuse goiters the enlargement may at first cause concern, but, as the speed and force of the circulation are reduced, congestion is diminished and the size of the gland decreases. Where the initial enlargement was not pronounced, the goiter tended to recede to barely palpable size in a comparatively short time.

In toxic adenoma the initial enlargement with treatment is not as noticeable and the recession takes place more slowly. In no instance in the entire series where the patient originally presented a palpable or visible thyroid enlargement has there been complete disappearance of the enlargement.

REACTIONS

Minor disturbances such as nausea, vomiting and epigastric cramping occurred in 5 patients: one each in two, eleven, fourteen, nineteen and twenty-four days. The initial dose was 0.6 Gm. in 3 and 0.8 Gm. in 2. Symptoms were promptly arrested in all by discontinuing the drug for two days and then resuming at a lower dosage level. One patient who suffered a gastric upset on the eleventh day and subsequently went on to remission after sixteen weeks' treatment developed a sore throat during the ninth month of treatment and two weeks later became quite ill with fever and a blotchy maculopapular eruption over the entire body. The drug was stopped and the symptoms promptly subsided. At the end of a week a single dose of 0.1 Gm. produced a similar reaction within a few hours. No further attempt at treatment has been made, and the patient has fortunately remained in remission for the past five months.

Three patients showed a fine morbilliform rash over the entire body, 2 of these within the first two weeks after treatment, and 1, significantly, before treatment was started. The latter patient provided a possible explanation for this type of rash, viz. miliaria due to the excess sweating that is so common in thyrotoxicosis. The drug was not discontinued, and the rash disappeared as soon as sweating decreased. Consideration should therefore be given this possible factor in the evaluation of any skin rash occurring in the course of treatment.

IODINE RESISTANT PATIENTS

Six iodine resistant patients have been observed. One who had also had x-ray therapy was brought under control in nine weeks, 1 in six weeks, 2 in four weeks and 1 in two weeks. The sixth patient, a woman aged 27 with a toxic diffuse goiter of six months' duration, was given iodine for three and one-half months without any response. The basal metabolic rate had dropped from plus 88 per cent to plus 66 per cent without decrease in toxicity. Iodine was discontinued and thiouracil started. The basal metabolic rate promptly rose to plus 88 per cent and then gradually dropped to plus 62 per cent in five weeks' time with a decrease in size of the goiter, lessening of toxicity, recession of the exophthalmos and a stabilization in body weight. She was discharged from the hospital and in two more weeks the basal metabolic rate was plus 35 per cent with further reduction in toxicity and a weight gain of 6 pounds (2.7 Kg.). To all appearance the patient was well on the way to the remission that was unattainable through the use of iodine.

RECURRENT HYPERTHYROIDISM

Five patients with recurrent hyperthyroidism following thyroidectomy are included in the group studied. One is a 75 year old man who had had thyroidectomy eighteen years before and who continued to have nervousness, tachycardia, tremor, exophthalmos and weight loss. At the beginning of treatment with thiouracil his basal metabolic rate was plus 51 per cent. There was no palpable thyroid tissue and he had had no iodine. He was clinically improved in four weeks and his basal metabolic rate was minus 8 per cent at the end of six weeks. He is now on a maintenance dose of 0.1 Gm. of thiouracil daily.

The second patient, a woman aged 31, had had a thyroidectomy for toxic diffuse goiter six years before and was well until three months before treatment was begun. Classic signs of toxic diffuse goiter, including a recurrent bilateral diffuse enlargement, with a basal metabolic rate of plus 27 per cent, were present. At the end of eight weeks the basal metabolic rate was minus 20 per cent and the thyroid enlargement had almost entirely disappeared. Maintenance dosage of 0.2 Gm. daily was continued for another eight weeks and then the drug was stopped. In three days palpitation, nervousness, diarrhea and weight loss developed; 0.4 Gm. of thiouracil daily has since subdued and is now controlling the disturbance.

A third patient, a man aged 40, had had a subtotal thyroidectomy for severe toxic diffuse goiter in 1940. In June 1943 nervousness, weight loss and exophthalmos returned and he was given iodine continuously until September 1944. There was little improvement, and diffuse enlargement of the thyroid, involving mainly the isthmus, had developed. The initial basal metabolic rate was plus 16 per cent (no iodine had been taken for six weeks prior to beginning treatment with thiouracil). On the twenty-fourth day of thiouracil therapy he developed chills, fever, nausea, vomiting and epigastric distress necessitating stopping the drug for one day and resuming it at half the starting dose. There was no more trouble, and on the reduced dosage the basal metabolic rate was minus 8 per cent by the end of the seventh week, he was decidedly improved, and the goiter was much smaller.

EFFECT ON PATIENTS WITH SLIGHT INCREASE IN METABOLIC RATE

Two patients with a slight increase in the metabolic rate have been observed. One was a woman aged 26 with symptoms of five months' duration (including palpitation, tremor, nervousness and smooth bilateral thyroid enlargement but no weight loss) and a basal metabolic rate of plus 8 per cent. (Her mother and an older brother had both had toxic diffuse goiters.) Improvement in symptoms and a drop in the basal metabolic rate to 0 followed after three weeks' treatment. Five months after beginning treatment she had a barely palpable gland and was symptom free on a maintenance dose of 0.1 Gm. of thiouracil daily.

The second patient, a man aged 39, had had nervousness and tremor for at least ten years. In April 1944 he suffered a nervous breakdown from which he had not fully recovered. There was no tachycardia or weight loss, but there was nervousness, fine tremor, warm, moist palms, and a small nodule in the thyroid isthmus. The initial basal metabolic rate was plus 5 per cent. Four weeks after starting thiouracil he reported definite improvement. He was less tired and

nervous, the tremor was diminished, and the weight had increased 2½ pounds (1 Kg.). The basal metabolic rate was minus 4 per cent and the adenoma was somewhat smaller.

While the experience with these 2 patients is too limited, it does indicate the importance of paying attention to slight increases in the rate of metabolism (the accepted normal standards of plus 10 or 15 per cent and minus 10 per cent might well be revised to plus 5 per cent and minus 20 per cent) and demonstrates the therapeutic and diagnostic value of treating such patients with thiouracil.

MYXEDEMA

Only 1 patient in the series developed myxedema in the course of treatment. A man aged 44 had a toxic diffuse goiter of two months' standing with an initial metabolism of plus 42 per cent. This had dropped to plus 18 per cent after four days of iodine administration. The response to thiouracil during the subsequent six weeks' treatment (0.8 Gm. daily) was quite satisfactory. All symptoms had improved, the thyroid enlargement had receded, there was a weight gain of 12 pounds (5.4 Kg.) and the basal metabolic rate was minus 12 per cent. Thiouracil was reduced to 0.6 Gm. daily for the next two weeks and then to 0.4 Gm. daily for three more weeks. Eleven weeks after treatment was started the basal metabolic rate was minus 17 per cent, and the weight had increased a total of 16 pounds (7.3 Kg.). At this time there was noted puffiness about the eyes, pallor of the skin, sluggish movements and speech and a slow pulse. The patient also complained of being "slowed up." Thiouracil was reduced to 0.2 Gm. daily for the next two weeks, at the end of which there was some improvement, with a weight loss of 10 pounds (4.5 Kg.) and a drop in the basal metabolic rate to minus 10 per cent. The drug was then dropped for one week and resumed at 0.1 Gm. daily for the following three weeks, when the weight had dropped another 9 pounds (4 Kg.) the basal metabolic rate was 0, and all signs of myxedema had disappeared. Thiouracil was then stopped, but in three weeks' time there was return of tachycardia and nervousness and the basal metabolic rate was plus 10 per cent. The patient has since been under satisfactory control on 0.2 Gm. daily.

FIBRILLATION

Two women, one aged 66 with a toxic diffuse goiter, the other aged 76 with a toxic adenoma, had fibrillation with decompensation. Compensation with normal sinus rhythm was restored after six weeks and eight weeks respectively of thiouracil therapy.

RESISTANCE

Only 1 patient failed to respond to treatment. A man aged 40 with diabetes mellitus and an active toxic ademona of eight years' standing showed control of diabetes and partial control of hyperthyroidism by iodization over a period of six years. In August 1943 thiouracil 0.8 Gm. daily was substituted for the iodine. The initial basal metabolic rate was plus 13 per cent. No change in weight, drop in basal metabolic rate, decrease in symptoms or diminution in the daily 40 unit requirement of insulin occurred. At the end of eight months the basal metabolic rate was plus 18 per cent. Thiouracil was increased to 1 Gm. daily for two weeks and with no change in basal metabolic rate was raised to 1.2 Gm. daily for the following three weeks. At this point the basal metabolic rate was plus 31 per cent and the drug was discontinued after nine months' continuous administration. This was early in May 1944. Observations at monthly intervals showed no change in his condition, with basal metabolic readings of plus 29, plus 20 and plus 25 per cent. Then for the first time in seven years the basal metabolic rate was plus 5 per cent, then minus 3 per cent, plus 3 per cent and plus 20 per cent (Nov. 7, 1944). He had been free from nervousness, tremor and tachycardia during the three months of lowered metabolism (with no change in the status of the diabetes), but these symptoms recurred coincident with the rise in the basal metabolic rate to plus 20 per cent; 0.4 Gm. of thiouracil daily was started, but after two weeks the basal metabolic rate was plus 34 per cent with no change in symptoms. At present (December 1944) he is still taking 0.6 Gm. of thiouracil daily. The reason for this unusual failure to respond is not clear.

SUMMARY

In summarizing the clinical experience in the treatment of 32 patients, the following points appear significant:

An initial daily dose of 0.6 Gm. in three doses of 0.2 Gm. each appears adequate for all ordinary purposes. As clinical improvement sets in and the basal metabolic rate falls, the dose may be reduced to 0.2 Gm. twice daily (twelve hours apart). When the basal metabolic rate is stabilized between plus 5 per cent and minus 10 per cent, a maintenance dose of 0.1 to 0.3 Gm. is sufficient to keep the patient in remission. Observations should be made every two weeks at first and then every four weeks. Patients may be ambulatory.

Improvement occurred on an average in three weeks in patients with toxic diffuse goiters and in approximately nine weeks in those with toxic adenomas. Previous iodization delayed improvement in both types, with a more prolonged delay in those with toxic adenomas. Also in the previously iodized patients a rise in the basal metabolic rate is likely to occur during early thiouracil therapy because of loss of iodine effect.

Twenty-nine patients have responded favorably, 2 have not been treated long enough, and 1 is resistant to the drug. Of 5 patients in whom an attempt was made to stop treatment, 3 have relapsed, 1 is threatening to relapse and only 1 has remained in remission for five months. At present it is difficult to predict when and in whom to stop the drug.

Where thyroid enlargement was noted, the gland tended to increase in size and become softer in the first few weeks of treatment. Thereafter recession in size became more pronounced and occurred more rapidly in the toxic diffuse goiters than in the toxic adenomas.

Only 1 instance of drug sensitization was encountered in this series. Five patients developed nausea and epigastric distress early in therapy, and this promptly disappeared after discontinuing the drug for a few days and then resuming at a lower dosage level.

Patients who are iodine fast or resistant can be brought to remission with thiouracil. Those with recurrent hyperthyroidism (postsurgical) appear to be quite sensitive to thiouracil, responding quite promptly.

In the mild forms of hyperthyroidism or in the borderline cases, thiouracil may prove extremely useful both therapeutically and diagnostically. It would

appear preferable to adopt as the standard normal a basal metabolic rate of plus 5 per cent to minus 20 per cent.

Myxedema developed in only 1 patient in the series and was promptly controlled. Frequent observations and an awareness of this possibility should keep this risk at a low level.

Fibrillation and cardiac decompensation in the thyrocardiac may be promptly controlled with thiouracil.

An unexplained instance of resistance to thiouracil occurred in this series.

From the data presented, and from that which is rapidly accumulating, thiouracil appears to be the agent of choice in inducing and maintaining a state of remission in thyrotoxicosis.

PROBLEMS IN THE SURGICAL TREATMENT OF CONGENITAL MEGACOLON

RAWLEY M. PENICK JR., M.D.
NEW ORLEANS

The problems relating to the etiology and the proper treatment of congenital megacolon remain largely unsolved, although this uncommon condition has challenged the medical profession since Hirschsprung's report over fifty years ago. The literature on this subject is confusing and difficult to evaluate. Many articles consist in a report of a single case, the true nature of which is often doubtful, and those treated are too frequently followed only a few months.

In this communication an attempt is made to correlate our experience in the management of cases of congenital megacolon with the results of treatment of this disease in the hands of others. No attempt has been made to include reports of single cases, for any conclusions drawn from these might be misleading. The results in 11 patients on whom left lumbar sympathectomy was performed by the surgical staff at Tulane University School of Medicine and the Ochsner Clinic have been compared with results following this and other types of therapy previously reported. Likewise, a plan of management in such cases will be suggested.

CLINICAL TYPES

In conjunction with this study all cases in which a diagnosis of megacolon or questionable megacolon seen at two large general hospitals in New Orleans during the past ten years were reviewed. About 30 of these were found. In most instances the diagnosis was not established, although frequently there was radiographic evidence of colonic dilatation and the clinical findings were often confirmatory. Usually a few days of conservative treatment in the hospital sufficed. The subsequent course of these patients is not known, but it is significant that only 1 or 2 were readmitted to either hospital for a similar complaint. This would suggest that there exist mild forms of the disease which require special treatment only when unusual impaction occurs. On the other hand, the condition of the 11 patients treated by sympathectomy fulfilled all the criteria to support a diagnosis of congenital megacolon in its severe form. Operation was not performed if there was any doubt as to the nature of the disease or if it was thought that medical management would prove satisfactory.

The severe forms of megacolon vary both as to symptomatology and as to the condition of the intestine. This is evident in the 11 patients on whom sympathectomy was done. Ten of these had pronounced dilatation of the sigmoid with involvement of varying amounts of the remaining colon, whereas in 1 case (case 11) there was never any demonstrable abnormality of the descending colon, sigmoid or rectum over a period of four years. On numerous occasions radiographic studies with contrast mediums have shown this undilated colon to have a normal ability to expel material from its lumen. The remainder of this patient's colon was affected and later massive dilatation of the terminal ileum developed. These variations regarding the site and extent of involvement are confirmed by many writers. De Takats [1] believes that instead of the usual hypertrophy there are instances in which the intestinal wall is thin and the musculature defective; he points out that any type of treatment is liable to fail when this is present. There can be little doubt that the varied clinical types of megacolon have been a source of confusion in evaluating methods of treatment.

TREATMENT

Drug Therapy.—Clinical experience with selective drugs was unsatisfactory until Law [2] introduced the more stable cholines as parasympathetic stimulants. His results with mecholyl bromide, administered orally, have been promising and this undoubtedly constitutes an important milestone. It should be emphasized that drug therapy must be accompanied by a careful regimen to aid bowel function, particularly in the first few months of treatment. Details of this management are well described by Law.[3]

Beneficial effects have been reported from the use of syntropan, an atropine-like drug which acts as a parasympathetic paralyzant. Introduced by Klingman,[4] it has produced beneficial effects in some cases. The

From the Department of Surgery, Tulane University School of Medicine, and the Section on Surgery, Ochsner Clinic.

Dr. Alton Ochsner permitted the author to include his cases. He performed the operation in most of the cases in the series.

Read before the Section on Surgery, General and Abdominal, at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 14, 1944.

fact that both of these compounds, which have opposite effects, have given good results supports the often expressed contention that a perversion of the autonomic system is the fundamental fault.

Therapeutic Tests.—Spinal anesthesia frequently has a dramatic effect on these patients, and indeed there have been instances in which benefits have persisted for some time. When anesthesia is obtained in this way there is usually a large evacuation of the bowel, or sometimes several, in the following twenty-four hours. This phenomenon has been regarded as proof that expulsive power exists and is therefore considered a good omen, particularly if sympathectomy is to be performed. Too little exact information is available to justify a dogmatic opinion, but the failure of spinal anesthesia to cause spontaneous evacuation can probably be associated with failures in surgical intervention. Obviously, this question requires further study. Unfortunately, in our series this test was often neglected, but in the 1 instance of failure the effect of the anesthetic was poor.

collected from the literature covering an early period in the development of sympathetic surgery. Isolated instances are reported in which death occurred in debilitated infants, but these are not always representative. The safety of lumbar sympathectomy is further attested by the low operative mortality of this procedure for other conditions.

The relief obtained by left lumbar sympathectomy compares favorably with results following more extensive operations. In our series 11 patients were thus treated, in 7 of whom highly satisfactory results were obtained. Three others were greatly improved, but occasional cathartics or enemas are still required. One was a complete failure. This was not unexpected, for this patient had involvement of both colon and ileum and a spinal anesthetic had little effect preoperatively. Nine of the patients have been followed for from one to eleven years. The other 2 were not followed for as long a period, because 1 was a complete failure and 1 child seemed entirely well for three months following the operation, when he died from nephritis.

TABLE 2.—*Author's Cases of Megacolon Treated by Left Lumbar Sympathectomy*

Case	Age, Yrs.	Sex	Preoperative Condition	Date of Operation	Results
1. W. A.	2	♂	Bowel movement only with cathartics or enemas	4/ 3/40	Normal bowel movement since operation; died 60 days after operation from bronchopneumonia and acute nephritis
2. B. B.	3	♂	Constipation; projectile vomiting.....	6/ 9/43	Bowels move 1 or 2 times daily; cathartic about every 2 weeks
3. E. D.	9	♂	Bowel movement only with enema or cathartic	12/ 1/36	Had got along well until had vomiting on 6/11/40; bowels moved normally at discharge
4. A. F.	22	♀	Two admissions for distention and vomiting; 3d in labor, vomiting	2/ 3/41	Bowels apparently moving well
5. W. H.	22 mos.	♂	Bowel movement only with enemas or cathartics	3/20/39	Bowel movement daily without cathartics; x-ray 5/23/44 revealed moderate dilatation of distal half of colon
6. G. M.	1½	♂	Bowel movement only with enemas and cathartics	3/27/33	Bowels move daily; ½ oz. olive oil instilled into rectum daily; no cathartics; enema every 1 or 2 months, occasional vomiting; x-ray 6/5/44 revealed dilatation of left colon and sigmoid
7. E. M.	52	♂	5-6 days at time without bowel movement; x-rays; megacolon	9/23/37	Died of heart disease 5 years later; bowels apparently gave no trouble
8. C. Q.	7	♂	Bowel movement rarely without cathartic or enema	12/ 3/40	Bowels move daily; takes ½ oz. or liquid petrolatum; no cathartics or enemas; x-rays 4/5/44 revealed dilatation of descending colon and sigmoid
9. E. J.	2½	♂	Enema required for bowel movement	8/ 5/43	Bowel movement daily but given enema every 2 or 3 days; x-rays 3/28/44 revealed residual dilatation of entire colon
10. D. L.	3	♀	No bowel movement without cathartics or enemas	9/23/41	Bowel movement daily with liquid petrolatum; x-rays revealed residual dilatation, less than before operation
11. H. E.	3½	♂	Bowel movement only with cathartics or enema; resection of colon	10/12/43	Sympathectomy for dilatation of ileum; no improvement

De Takats [5] rightly regards this therapeutic test as important. He believes that certain of these patients have an atrophied bowel wall and that some indication of this can usually be obtained by preoperative study. This observer advocates the administration of a barium enema, after which a spinal anesthetic or acetylcholine bromide should be given by injection. Then, forty-five minutes later, another film should be made and the extent of the evacuation noted. De Takats [5] believes that the use of the drug is easier and safer than a spinal anesthetic, especially for debilitated infants. There is every indication that such studies are extremely valuable and should be carried out in each case.

Lumbar Sympathectomy.—Left lumbar sympathectomy is the simplest operative procedure that is justifiable. The mortality is practically nil in patients over 3 years of age and the results are as good as with any other operative method, except possibly more extensive sympathetic ablations. As will be seen in table 1, in all the larger series except one no deaths were reported. Passler [6] reported three deaths in 117 cases

Thus, 90 per cent of these patients were greatly benefited. There were no deaths from the operation, although the patients' ages ranged from 18 months to 52 years. Four patients (nine months and two, three and five years after operation) have been reexamined radiographically with contrast mediums; dilatation with some sluggishness of evacuation was demonstrated in each case. Although these findings indicate that the bowel does not become normal, there was less dilatation and retention than at the time of the original radiographic studies. This observation was also made by Telford and his associates.[7]

Results of lumbar sympathectomy reported in the literature indicate that satisfactory function is obtained in the great majority of patients (table 1). It would therefore seem to be the procedure of choice in all cases in which medical treatment has been ineffective. In my opinion the only question in regard to the performance of sympathectomy is whether more radical ablations should be carried out. Bilateral lumbar sympathectomy, excision of the superior hypogastric plexus with the presacral nerve, and a combination of lumbar

ganglionectomy with section of the splanchnics have all proved effective. The disadvantages of sympathetic surgery are few. Vascular changes in the lower extremity are of little moment. Sterility, however, is a distinct disadvantage of bilateral ablation, and for this reason unilateral sympathectomy should be tried before resorting to more radical procedures.

Indications and Contraindications for Left Lumbar Sympathectomy.—1. The history should be compatible with the diagnosis of congenital megacolon.

2. Mechanical obstructions must be ruled out by roentgenographic studies, therapeutic tests and other examinations.

3. Persistent dilatation of the bowel must be demonstrated by radiographic studies following the administration of a barium enema.

4. Failure or partial failure of medical treatment (including the newer drugs) must have been demonstrated. A partial failure might be arbitrarily defined as one in which more than one enema or cathartic a week is necessary in a child under proper medical regimen or in adults more than two enemas or cathartics. The presence of another unrelated disease or a condition requiring curtailment of activity should be taken into consideration when these are present.

5. Probably the therapeutic test should be positive. However, a negative result from the injection of a spinal anesthetic or parasympathetic stimulants is not known to be a definite contraindication to sympathectomy, although in some instances it has proved to be an omen of failure.

6. Sympathectomy on patients less than 2½ years of age is contraindicated unless it is felt that this might be a life-saving measure. Most patients can be treated conservatively until 2½ or 3 years of age.

Radical Sympathetic Surgery.—It should be stated frankly that no one knows exactly how much of the sympathetic system should be removed to obtain the best results. My own experience throws little light on this subject except to testify that left lumbar sympathectomy has proved highly satisfactory. It would seem logical to reserve the more radical operations for those instances in which unilateral ablation of the lumbar chain has been accompanied by some beneficial effect but not enough to be considered satisfactory. These operations lend themselves readily to staged procedures.

Resection of Intestine.—This formidable operation has been advocated by many surgeons. Two of the latest favorable articles are those by Whitehouse, Bargen and Dixon [8] and Yeazell and Bell.[9] The results reported by these authors are shown in table 1. One series of 29 cases showed a mortality of 24 per cent even though 11 were 20 years of age or older. Over 50 per cent of the patients were 15 years of age or more. This mortality rate emphasizes the hazard of resection. On the other hand, in the other series of 6 cases there were no fatalities. The ages of these patients were between 3½ and 12 years. These authors recommend resection when therapeutic tests are unsatisfactory, for in their hands sympathectomy then produced inadequate improvement. Removal of the intestine gives best results in older patients and in those with involvement of small amounts of intestine.

COMMENT

Our meager knowledge of this disease makes any plan of treatment vulnerable to adverse criticism. Nevertheless, some plan of management is desirable and will prove useful even though it is necessarily tentative. The following seems logical in light of our present information:

The diagnosis, of course, should be supported by adequate observation and study of the patient. A therapeutic test with acetylcholine or a spinal anesthetic should be carried out in each case and surgical intervention should not be contemplated until medical management, utilizing the sympathetic stimulants, has had a trial of eight to ten weeks. Rarely, emergency operations might be indicated. It is inadvisable to subject any patient less than 2½ years of age to any surgical procedure unless it is a life-saving measure. Conservative management, even though not entirely satisfactory, is the treatment of choice in infants.

If, then, the medical regimen does not prove highly satisfactory and the age of 3 has been reached, left lumbar sympathectomy is indicated, particularly if spinal anesthesia produces a copious bowel movement. Should this fail, one has to decide whether the right lumbar chain is to be removed or the splanchnics on the right. These operations can be done in stages.

Failure to gain any improvement after left lumbar ganglionectomy might be considered as evidence that further sympathetic surgical measures are contraindicated but some improvement would warrant bilateral operation. Certainly, if no improvement followed bilateral ganglionectomy, one would hesitate to do more.

In my estimation, intestinal resection should be resorted to only after medical management and sympathetic surgical measures have failed.

3503 Prytania Street.

ABSTRACT OF DISCUSSION

DR. J. ARNOLD BARGEN, Rochester, Minn.: The procedure of choice seems to be a one stage extraperitoneal resection, leaving the patient with a temporary double barreled colostomy, the stoma of which can be closed at a later date. Such a surgical procedure does not seem suitable for the treatment of infants with megacolon or children under 5 years of age. It is the procedure or treatment of choice of patients who have not responded to sympathectomy or to medical treatment. The medical treatment employed has consisted in the repeated thorough emptying of the colon, the administration of mecholyl bromide, neostigmine bromide or syntropan and the use of spinal anesthesia and other parasympathetic paralyzants and sympathetic stimulants. If the megacolon does not respond to spinal anesthesia, sympathectomy will have doubtful value. Degenerative changes occur in the plexus of Auerbach, including reduction in size in the ganglion cells and fibers, vacuolation of the cells and at times absence or at least imperfect formation of the ganglion cells. Sympathectomy can at best be expected to cause improvement by a so-called flanking movement. Good bowel evacuation may follow this procedure, but a return to relative normality of the hugely hypertrophied colon can be expected in only the occasional case. I agree with the general implications of Dr. Penick's list of indications for sympathectomy. I would favor postponing any surgery of this type or resection even longer, say to the age of 5. Mention should be made of the often repeated observation that sympathectomy may result in sterility in men. This condition is vastly predominant in males in the ratio of about 5 to 1. When all these things are kept in mind, the operation will have a somewhat limited application. This is in no way meant to condemn it, but I would like to suggest that it is only one of the surgical procedures applicable in the treatment of megacolon. The results

of resection are uniformly good and permanent, as is attested by a follow-up of our series of cases from three to thirty-two years after operation. That the problem of megacolon is not generally well understood is illustrated by the fact that 1 young man of whom I know with a huge megacolon was inducted into active military service and only after convincing the officials that he had a bowel movement only every two months was he mustered out and returned to civilian life.

DR. REGINALD H. SMITHWICK, Boston: Resection of portions of the sympathetic supply to the bowel have been helpful. The results in Dr. Penick's series of 11 cases seem unusually satisfactory. They have been followed a sufficient time to be significant, but it will be important to check them repeatedly as the years go by. I am in accord with Dr. Penick's remarks regarding multiple stage procedures, starting with left lumbar sympathectomy and proceeding with a right lumbar sympathectomy, with or without splanchnicectomy later, if necessary. The retroperitoneal approach is simple and carries little risk. A unilateral lumbar sympathectomy will not interfere with ejaculation, but a bilateral sympathectomy occasionally may, even if both first lumbar ganglions are preserved. Detailed studies should be carried out before operation and between steps. These should include barium studies before and after spinal anesthesia and, when possible, paravertebral procaine block to determine the reaction of the bowel to acute sympathetic denervation. The effect of drugs which stimulate the parasympathetic supply should be studied. Unfortunately, there are no drugs which effectively inhibit sympathetic activity. I believe that routine colonimetric studies would cast further light on this problem and should be included among preoperative tests. This disease is rare, and the opportunity for any one physician to study and treat these patients does not arise very often. It will be necessary to resort to resection of various portions of the colon at times. If the diagnostic tests offer encouragement, sympathectomy should be the first maneuver. The results of resection have been marred by a high operative mortality, but the late results may be excellent. There is every reason to believe that with better preoperative preparation and with improved surgical technic the mortality of resection can be lowered.

DR. K. S. GRIMSON, Durham, N. C.: I should like to present conclusions derived from a review of 24 megacolon patients that have led to a more conservative attitude toward sympathectomy than has been presented today. The late mortality rates of megacolon reported after long term studies may be as high as 79 per cent. Sympathectomy is performed with a low immediate operative risk. The pathologic condition is, however, little altered by the sympathectomy and many patients have late difficulty. Four patients in this group were sympathectomized. Two have since died. A third required colon resection. Three varieties of megacolon were encountered among the 24 patients reviewed. One group including 12 patients presented uniform involvement of the entire colon and the rectum. Eight are now living and well, 1 died three years after a sympathectomy and 3 have moderately severe disability. A second group including 7 patients had involvement of all of the colon down to the midsigmoid region and a normal lower sigmoid colon and rectum. Four patients died. Sympathectomy failed in 2. Three treated by resection of the megacolon and ileosigmoidostomy are well. A third group including 5 patients presented enormous involvement of the sigmoid and descending colon. These 5 are responding to continued conservative treatment. The review suggests that protracted medical management may be indicated in the groups 1 and 3 varieties of megacolon. Medical management may be facilitated by the sympathectomy, but interruption of sensory pathways may later lead to difficulty. Complete megacolon resection and anastomosis between the normal ileum and the normal lower sigmoid colon seems indicated for patients with megacolon of the second variety that resists medical management.

DR. ARTHUR W. ALLEN, Boston: We do not regard lumbar sympathectomy as a difficult or serious operation in the Massachusetts General Hospital. It is done by the general surgical resident staff through a retroperitoneal incision. The patients are out of bed the next day or certainly the day after following the operation. We are indebted largely to Dr. Smithwick for working out an exposure through the loin that is simple and safe. I therefore can answer Dr. Coller and say that we do not regard it as an operation that has to be done by a trained neurosurgeon.

THE CHAIRMAN: Dr. Smithwick, do you agree to that?

DR. REGINALD H. SMITHWICK, Boston: Yes, I think that is a fair statement.

THE CHAIRMAN: In our hospital we feel the same. The operation is done by assistant residents and residents. We use the peritoneal approach and do not regard it as a major operation. The patient can be up the next day or even the same day.

DR. RAWLEY M. PENICK JR., New Orleans: We regard sympathectomy in much the same light as do Dr. Allen and Dr. Coller. The operation is performed usually by the general surgical staff rather than by the neurosurgeon. This operation can be done safely on elderly people and not necessarily for megacolon; it is also a safe procedure in young infants. One of these patients was 18 months old and there were no deaths. Its low mortality rate, simplicity and safety seem to be the chief advantages of sympathectomy. Furthermore, unilateral sympathectomy will cause so little significant change in the patient that it seems to me it should be tried in every case before a more radical procedure is contemplated. I agree with Dr. Grimson that, not infrequently, a normal segment of sigmoid is present above the pelvic floor. This permits an anastomosis after resection.

PERNICIOUS ANEMIA AND THE EARLY DIAGNOSIS OF TUMORS OF THE STOMACH

LEO G. RIGLER, M.D.
HENRY S. KAPLAN, M.D.
MINNEAPOLIS
AND
CAPTAIN DANIEL L. FINK
MEDICAL CORPS, ARMY OF THE UNITED STATES

Efforts at the recognition of carcinoma of the stomach at an early stage, when surgery would have some likelihood of success, have been pursued for many years with indifferent success. Despite the expansion of roentgen diagnosis, the more general use of gastroscopy, the refinement of the methods of examination of the gastric contents and stool, the record is a black one. The overall salvage of but 2 per cent of the patients afflicted with this disease or even the survival of 6 per cent, which is the maximum reported, gives a picture of the difficulties involved. Obviously, not all of the poor results are the consequence of late diagnosis, since many cases would not be cured regardless of the time when the diagnosis was established, but a great improvement might be achieved if the diagnosis was accomplished at an earlier stage.

The major factors in the late recognition of carcinoma of the stomach are its insidious onset, the absence of striking symptoms occurring even in advanced tumors, and the difficulties of establishing the diagnosis. While roentgen examination is generally considered the most accurate and widely applicable procedure, yet here too errors in the diagnosis of smaller tumors may well be more frequent than is now generally admitted. Statistics indicating an accuracy of 95 to 98 per cent in the roentgen diagnosis of carcinoma of the stomach have been published. On the positive side at least it must be borne in mind that they are based to a large extent

Dr. Kaplan is trainee of the National Cancer Institute.
Read before the Section on Radiology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 14, 1944.
From the Department of Radiology and Physical Therapy of the University of Minnesota and the University and Minneapolis General Hospitals (Captain Fink).

on well developed, easily recognized, symptom-producing tumors, most of which are already inoperable. What would be the overall accuracy of diagnosis if large numbers of symptomless individuals were examined so that a high percentage of small lesions would be encountered? There is no exact information on this score, although we know from various reports that such small lesions may occasionally be demonstrated.[1] To indicate this possibility, figure 1 is reproduced. Here a benign polyp about 4 mm. in diameter, occurring in a patient with pernicious anemia, is clearly demonstrated as distinct from the shadows produced by the folds of the mucous membrane. However, this small tumor was found only after it had been observed gastroscopically by Dr. Richard Varco and reexamination had been done to demonstrate it. We have observed other lesions but slightly larger than this, but in all probability many such may be overlooked.

In an effort to test out the accuracy of the roentgen method in symptomless individuals, a project was considered many years ago to examine routinely the stomachs of all men past the age of 40 at semiannual intervals. A study of the statistics on the incidence of gastric cancer in the living population over the age of 40 as has recently been reported by Collins, Gover and Dorn[2] would indicate that certainly not more than 3 persons per thousand would be likely to have the disease at any one time. Considering the expensive, painstaking, time-consuming character of the x-ray examination of the stomach, such a procedure seemed relatively unproductive. The recent report of St. John, Swenson and Harvey[3] bears out the correctness of this assumption. They found but 3 tumors in over 2,400 symptomless persons above the age of 50. It seemed more reasonable to examine a selected group of persons in whom the incidence would be likely to be much higher. There are a number of such categories, but a review of the literature seemed to indicate that patients with pernicious anemia would offer the most productive results. Accordingly, in 1939 we undertook to examine roentgenologically all our patients with pernicious anemia at semiannual intervals.

The coexistence of pernicious anemia and carcinoma of the stomach in the same person has had extensive study since it was first observed by Quincke in 1876. Numerous case reports, studies of clinical cases and a few studies of autopsy series have appeared. The literature has been adequately reviewed in recent papers.[4] That such an association exists seems well established, although there is a difference of opinion as to its frequency. It is evident that there has been an increase in the incidence of the coexistence of the two diseases, which is best illustrated by the various reports[5] from the Mayo Clinic during the last twenty years. Such a trend may in part be due to the better recognition of gastric tumors but may well be due to the increased longevity of patients with pernicious anemia resulting from the institution of liver therapy. In all the case reports there is a vast preponderance of individuals in whom gastric tumors are discovered either some time after (as long as seventeen years) or simultaneously with the discovery of the pernicious anemia.

Several possibilities exist to explain the relationship between pernicious anemia and carcinoma of the stomach. Is it an accidental association of two diseases occurring in the same age group? Or does carcinoma of the stomach produce a pernicious anemia-like picture or possibly a true pernicious anemia? Conversely, does pernicious anemia of itself produce carcinoma of the stomach? Finally, is there a common precursor for the two diseases which tends to produce either or both and thereby a close association?

The paper of Jenner[6] was perhaps the first to bring home forcefully that the association of the two diseases was not accidental. In a series of 181 living patients with well established pernicious anemia he found carcinoma of the stomach in 4.4 per cent, which he calculated to be approximately twelve times as frequent as in the rest of the living population of the same age and sex.

FIG. 1.—Spot film of the stomach of a patient with pernicious anemia demonstrating a benign polyp 4 mm. in diameter (arrow). The lesion was not seen on first examination, was found gastroscopically and was then observed on reexamination.

Other clinical studies give varying figures. The last one of Doehring and Eusterman[7] in over 1,000 cases of pernicious anemia reveals an incidence of carcinoma of the stomach in 1.6 per cent.

Autopsy studies have been unsatisfactory because of the tendency of the pathologist to discard the diagnosis of pernicious anemia when confronted by a tumor of the stomach. Nevertheless, some striking findings have been thus obtained. Kaplan and Rigler[8] have reviewed the literature on autopsy studies and reported their own investigation of 43,021 consecutive autopsies, in which approximately 293 cases of [illegible] were found in persons over the age [illegible] cases of carcinoma of the stomach were present in this group, an incidence of association of 12.3 per cent. This is over three times as great an incidence of carcinoma of the stomach as in the remainder of the same

age group of the autopsy series. This study seems to establish beyond peradventure that the coincidence of the two diseases is not accidental, although the underlying cause of the association is not definitely known.

With the establishment of firm criteria for the diagnosis of pernicious anemia [9] it is usually possible to distinguish sharply between the anemia of carcinoma and a true primary type. The coincidence of small tumors of the stomach with pernicious anemia makes it unreasonable to suppose that the tumor could possibly destroy all the mucosa which produces intrinsic factor. Therefore the second possibility seems excluded. The possibility that pernicious anemia may in some way cause the development of cancer of the stomach cannot be ruled out, but there is no evidence to support it.

Most investigators have concluded that there is a common precursor of the two diseases. Konjetzny [10] stressed the role of chronic gastritis as a constant accompaniment of carcinoma of the stomach. Hurst [11] and Faber [12] likewise believed that some type of chronic inflammation produced the atrophy of the gastric mucosa which is found in pernicious anemia, and Hurst [11] has felt that the latter may well be a precursor of gastric tumors. However, there is considerable evidence, especially that of Magnus and Ungley,[13] with regard to pernicious anemia, and of Guiss and Stewart [14] in regard to carcinoma, which indicates that gastritis is not an important factor.

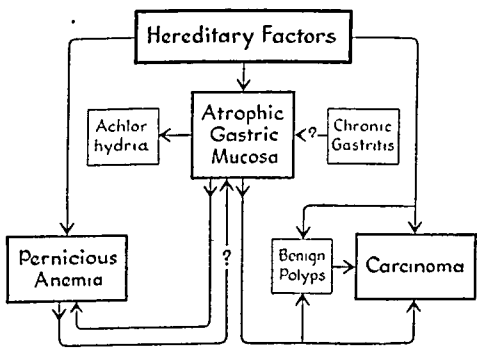

Fig. 2.—Hypothetical relationship of pernicious anemia to tumors of the stomach in schematic form. The major factor in both diseases may be hereditary, with an atrophic gastric mucosa as the immediate precursor. The atrophy may be due to chronic gastritis, but this is very doubtful. It may also follow rather than precede the pernicious anemia, but this also is questionable. Achlorhydria is related through the atrophic mucosa. Benign polyps frequently develop into carcinoma

Numerous other studies point to a hereditary or familial deficiency which predisposes to both diseases.

Figure 2 presents a hypothetical relationship between achlorhydria, pernicious anemia, benign polyps and carcinoma of the stomach. The development of any or all of these conditions from a common precursor related to atrophy of the gastric mucosa is certainly not yet established, but the diagrammatic relationship here shown expresses best our present knowledge of the subject.

There is another phase of this problem which deserves particular attention, namely the relationship of benign polypi of the stomach to pernicious anemia and also to carcinoma of the stomach. Various investigators, most notably Schindler,[15] Velde [16] and Brown,[17] have found that benign polypi are even more frequent than carcinoma in patients with pernicious anemia.

The relationship of polypi to carcinoma of the stomach has already been fully discussed by Stewart,[18] Miller, Eliason and Wright,[19] Rigler and Erickson,[20] Haring,[21] Benedict and Allen [22] and McRoberts.[23] There seems no doubt that many, although not all, benign epithelial tumors of the stomach may become cancers. Hence the discovery of a polyp of the stomach has great significance; in any effort to effect a reduction in the number of cases of carcinoma of the stomach, the radical treatment of such polyps must be given serious consideration. The possibility of the malignant degeneration of a polyp should be particularly borne in mind in cases of pernicious anemia because of the tendency of the latter to develop carcinoma.

The present report concerns itself with 211 patients with pernicious anemia on whom roentgen studies of the stomach with a barium meal were done. In approximately 20 per cent only one examination was made, usually at the time of the discovery of the anemia. In the remaining 80 per cent there were multiple examinations, usually done semiannually but often at longer intervals. In some cases as many as eight roentgen examinations of the stomach have been accomplished. Painstaking efforts have been made to reveal not only carcinoma but also benign polyps.

The diagnosis of pernicious anemia in these cases was established by the blood smears, bone marrow studies, the presence of glossitis, the findings of subacute combined sclerosis, an achlorhydria after histamine, and by the clinical and hematologic response to liver therapy. Critical review has been made in each case, and many of doubtful character have been discarded. Despite the difficulties which often attend the diagnosis of pernicious anemia, there is little doubt in our minds as to the authenticity of the diagnosis in these cases.

In many of these persons gastroscopy and in all of them careful studies of the gastric contents and of the stool have been made. Almost all of the reports of carcinoma have been confirmed by surgery or by autopsy. In a few cases there has been no such confirmation, but when the findings were doubtful the case

has been discarded. Many of the benign tumor cases have likewise been confirmed, although in these the possibilities of error are somewhat greater. It is our considered opinion, based on these various confirmatory data, that the diagnoses of gastric tumors are at least 90 per cent correct; more likely the error is much less. On the other hand there may well be a number of gastric tumors which we have so far failed to detect.

The results of the study are given in the accompanying table. It is obvious that the incidence shown is far higher than any heretofore published; it may be compared with the recent study of Doehring and Eusterman,[7] who found carcinoma of the stomach in 1.6 per cent of 1,014 cases of pernicious anemia. The striking difference between our finding and that of approximately 0.1 per cent found in a routine study of men over 50 without pernicious anemia [3] gives some idea of the vast difference between the frequency of gastric carcinoma in patients with pernicious anemia and of the remainder of the living population. Reference should again be made to the statistics of Collins, Gover and Dorn,[2] who estimated that 0.3 per cent of the living population over the age of 45 would have carcinoma of the stomach.

There are several explanations for this high incidence. The series is relatively small, so that the figures may be somewhat lower when more cases are seen, but it is not likely that the percentage will change to a significant degree.

Results of the Study

Total Cases of Pernicious Anemia Examined	Carcinoma of Stomach Found		Benign Tumors of Stomach Found		Total Tumors of Stomach Found	
211	17	8.0%	15	7.1%	32	15.1%

Unusually careful attention has been paid to the detection of small tumors which may have contributed to this high incidence. As might be expected, several positive errors have resulted. In 1 instance a most unusual calcification of the vessels of the cardiac end of the stomach produced a simulation of carcinoma. In another a diffuse antral spasm which persisted on several examinations was mistaken for carcinoma. These are cited to indicate that error in the positive roentgen diagnosis of carcinoma will result if an effort is made to diagnose small lesions in symptomless persons.

Most important of all in the attainment of so high an incidence are the repeated examinations to which this group of patients has been subjected. In many instances the lesion was not discovered on the first or even the second examination. It is obvious that if it were possible to reexamine all persons frequently until their decease, the incidence of carcinoma clinically observed would eventually approach closely the actual incidence found at autopsy. Thus, if 1,000 persons selected at random, all 50 years of age, were examined at any one time, they would show a relatively small incidence of carcinoma of the stomach. If the examinations were repeated semiannually until the decease of all of them, a final figure of approximately 4 per cent would be attained if the examinations were at all accurate. In the same way in pernicious anemia patients, if the examinations are persisted in long enough an incidence of at least 12 per cent should eventually be found.

Certain outstanding features characterized the findings in the series. The change from an apparently benign to a malignant tumor is well illustrated in a number of instances and is demonstrated in the following case report:

W. S., a man aged 68, gave a history of anemia for many years. In 1934 he was first admitted to the University Hospital, where the diagnosis of pernicious anemia was established. The blood findings were characteristic, and the presence of glossitis and other changes established the diagnosis unequivocally. There was an achlorhydria. Roentgen examination of the stomach was done, and it appeared to be entirely negative. He was given therapy with liver and improved.

He came to the Minneapolis General Hospital on April 14, 1941, at which time he appeared to be having a relapse. Sternal aspiration biopsy revealed a characteristic megaloblastic bone marrow. He had no gastrointestinal complaints except for poor appetite, which had been present for a great many years. Roentgen examination was done as a matter of routine. On the first examination some enlargement of the folds of mucous membrane in the antrum of the stomach were found (fig. 3 *a*). Reexamination a month later demonstrated a large polyp on the posterior wall of the middle third of the stomach (fig. 3 *b*).

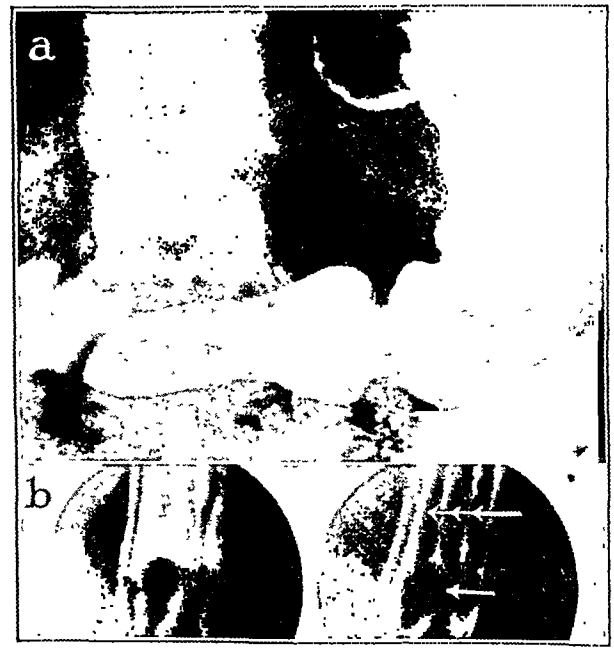

Fig. 3 (W. S.).—Stomach of a patient with pernicious anemia: *a*, filled stomach showing normal contours and peristalsis; *b*, spot films made one month later showing rounded, sharply defined filling defect (lower arrow) in middle third of stomach distinct from normal mucous membrane folds (arrows), characteristic of benign polyp.

The defect was rounded, sharply defined and very readily movable. The gastric wall showed flexibility and good peristalsis throughout the whole area. Gastroscopy was done three weeks later and revealed a single polyp in the middle third of the stomach, which appeared to have all the characteristics of a benign lesion. Surgery was advised at this time but was refused, and the patient left the hospital. He returned thirteen months later, complaining of loss of weight and appetite. This had commenced in January, that is about eight months after the discovery of the polyp, and he had noted black stools in the interim. The anemia had become much more severe. Reexamination at this time (fig. 4) showed an extensive carcinoma involving most of the stomach. He went rapidly down hill and died June 1, 1942, with extensive metastases.

The progression from pernicious anemia through gastric polyps to a full-blown gastric carcinoma is well illustrated in this instance. The outcome was most unfortunate, possibly owing to the refusal of the patient to accept operation when the polyp was first discovered. It is of coursse impossible to exclude some malignant

degeneration at that time, but the whole appearance, both roentgenologically and gastroscopically, was that of a benign noninfiltrating lesion. What the result would have been if he had submitted to operation, as advised originally, no one can accurately predict. We do know that the roentgen examination of the stomach, despite the absence of symptoms, permitted the early diagnosis of a gastric tumor at what appeared to be a curable stage.

A number of other cases have exhibited this same finding of a lesion which appeared to be benign and later became malignant. In such instances the microscopic examination of the stomach removed at operation may show mixtures of benign and malignant lesions, as illustrated in figure 5. Sections from two portions of the same gastric polyp, removed surgically from a patient with pernicious anemia, show a typical benign papilloma in one portion (fig. 5 *A*) and a typical invasive carcinoma in another portion (fig. 5 *B*).

The presence of a moderate or even large carcinoma of the stomach in a patient without any gastric symptoms whatever has been a common experience. The salvage of such cases by surgery, as a result of the discovery of the tumor because of this routine procedure in patients with pernicious anemia, has been strikingly illustrated in a number of instances and is a gratifying result of this study. A case in point follows:

M. F., a woman aged 57, was first seen on May 15, 1936 complaining of numbness of the extremities and weakness. Hemoglobin was 76 per cent, the red blood cell count was 3,200,000 and there was complete achlorhydria after histamine.

Fig. 4 (W. S.).—Appearance thirteen months after figure 3 *b*, showing extensive carcinoma of stomach which was found to be inoperable

The blood smears were somewhat atypical for pernicious anemia. Liver therapy was instituted and she gave a good response. The numbness persisted. Later examination of the blood established unequivocally the diagnosis of pernicious anemia.

Roentgen examination of the stomach was done in 1936 as a routine procedure and was found to be negative. The patient was not reexamined until her return, after the institution of the repeated examination program previously described. She was again examined Sept. 9, 1940, although she had absolutely no gastric symptoms. Three large defects were found in the stomach (fig. 6), two of which appeared closely connected. They were sharply defined but not entirely movable, and there was some invasion of the greater curvature, indicating that these were polypoid lesions which had undergone malignant

Fig. 5.—Sections of a tumor of the stomach removed surgically from a patient with pernicious anemia, to indicate malignant degeneration of a benign papilloma: *a*, section of a portion of tumor showing typical benign papilloma with hyperplasia of glands; *b*, section of another portion of same tumor showing anaplasia, loss of gland formation and invasion of muscularis, characteristic of carcinoma. The sections are slightly reduced from photomicrographs with magnifications *a* of 65 and *b* of 100 diameters

degeneration. It is notable that the defects are not seen at all in the filled stomach (fig. 6 *a*) but only in films with pressure applied (fig. 6 *b*).

Gastroscopy was done September 18 and showed some questionable infiltration. The polyps themselves were not clearly visualized. September 23 subtotal gastrectomy was done by Dr. O. H. Wangensteen, and the tumors were found in the middle portion of the stomach as described.

Examination of the excised specimen by Dr. Robert Hebbel revealed that external evidences of cancer were entirely lacking; near the greater curvature on the posterior wall were found two polypoid masses. One, immediately adjacent to the greater curvature, measured 2 by 2 by 1 cm. and was suspended on a relatively narrow pedicle, while the second measured 6 by 3 cm. and was proximal to the smaller mass. The tumors were soft and papillary and their surface was partially hemorrhagic. Between the polypoid masses there was an indurated, opaque, gelatinous thickening of the mucosa extending over

an area of about 1.5 cm. in diameter. No gross involvement of the submucosa was found microscopically. The polypoid masses showed papillary processes of various sizes and shapes. The tumors were not far removed from the structure of a benign polyp, but there was some histologic evidence of malignant change. The various sections were similar to those shown in figure 5. The conclusions were superficial polypoid adenocarcinoma of the stomach The patient recovered, and at the present time she is still well She has gained 5 pounds (2.3 Kg.) since the operation, but her pernicious anemia appears to be in much the same situation. Further liver extract has been given, and on last report her hemoglobin was 14 2 Gm. and the red cell count was 4,600,000

It is notable that this patient had no gastric symptoms whatever. Further questioning after the discovery of the x-ray findings elicited no complaints referable to the stomach. This is characteristic of patients with benign polyps, and the lesions found were certainly benign in origin, although malignant degeneration had already occurred.

The sequence of events here, namely atrophic gastric mucous membrane with pernicious anemia to benign polyp to adenocarcinoma, is strikingly brought out in this case. The tumors were easily diagnosed roentgenologically. They were in a relatively early stage and might well have continued on to an extensive cancer if the examination had been delayed until gastric symptoms appeared. It should be noted that gastroscopy failed to demonstrate these lesions. It is cases of this type which give some hope for the cure of carcinoma of the stomach. Such a case found on routine examination thoroughly justifies the numerous negative examinations which attend such a routine procedure.

A rather unfortunate outcome of the failure to repeat routine examination has occurred in a number of these patients. Because of the difficulties of any outpatient clinic, especially the lack of cooperation on the part of the patient, many of these persons have not returned for semiannual examinations, as previously indicated. Furthermore, physicians may be reluctant to accept minor lesions in patients who have no symptoms and are likely to fail to press the necessity for repeated examination. The following case illustrates this point:

G. R., a man aged 70, was first seen on Aug. 5, 1943 complaining of edema of the ankles, weakness and dyspnea. The gastrointestinal history was negative. On neurologic examination he had evidences of subacute combined degeneration. The hemoglobin was 36 per cent, with a red count of 1,350,000 and 6,300 leukocytes. The reticulocyte count was found to be 2 per cent. Gastric expression showed complete achlorhydria after histamine. Clear evidences of pernicious anemia were obtained, and liver therapy was instituted with a prompt and satisfactory result. The hemoglobin rose to 83 per cent and was maintained there constantly. On August 12 roentgen examination of the stomach and duodenum was done as a routine procedure and was negative.

Fig. 6 (M. R.).—Stomach of a patient with pernicious anemia without gastric symptoms: *a*, barium filled stomach without pressure; the tumor defects can scarcely be seen; *b*, pressure applied reveals three large filling defects (arrows) with some evidences of infiltration. Benign polypi with malignant changes were found at surgery

Reexamination was made on Feb. 5, 1940 (fig. 7 *a*). There were some changes found on the lesser curvature in the middle third of the stomach, minimal in extent, suggesting the possibility of carcinoma or polyp The findings were not sufficiently definite to justify surgery. Gastroscopy was done February 28 and reported as negative. It was repeated April 16 and again found negative except for atrophy of the gastric mucosa. An increase in the amount of liver resulted in a rise in the hemoglobin to 88 per cent, which was maintained.

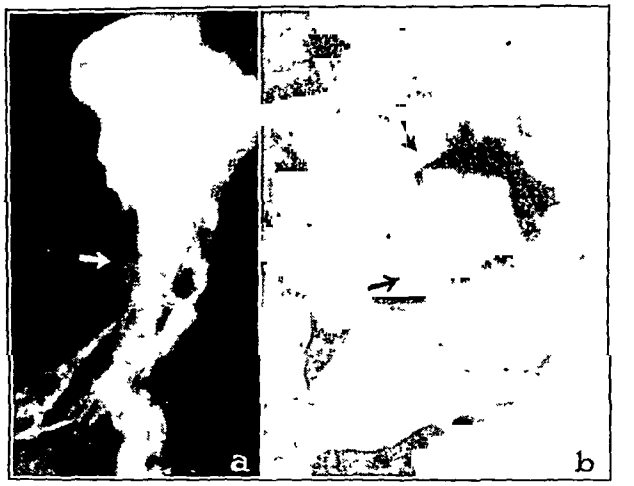

Fig. 7 (G. R.).—Stomach of a patient with pernicious anemia, showing early and late stages of carcinoma: *a*, examination Feb. 5, 1940, showing minimal defect on lesser curvature; *b*, stomach two years later, with extensive polypoid carcinoma, later found to be inoperable.

Unfortunately, this patient did not return for reexamination semiannually. He was seen again Nov. 27, 1941, complaining of gastric distress, but the physician was not impressed and no roentgen examination was undertaken.

He had some indigestion in January 1942, but it was so minor that it did not attract his attention at the time. January 27, almost two years after the previous study, he was reexamined roengenologically as a routine procedure. An extensive polypoid carcinoma of the stomach was found (fig. 7 *b*) at the site of the previous changes (fig. 7 *a*). Surgery was undertaken, but extensive metastases were found The tumor of the stomach was of the bulky type and measured 10 cm. in length. He died in August of 1942.

Reexamination at six month intervals would likely have resulted in the discovery of this tumor some eighteen months earlier, at which time surgery might well have been successful. No doubt the first stages of the lesion were present in February of 1940. Unfortunately the two negative gastroscopies and the improvement after liver therapy, together with the uncertainty of the roentgen diagnosis, led to a false sense of security. The relative absence of gastric symptoms even later when the tumor was already inoperable should be noted.

In the entire group the lack of symptoms was outstanding. In 1 patient who looked the picture of health and had not a symptom, whose hemoglobin was 90 per cent and whose red blood cell count was normal, a lesion with extensive metastases was found. Only the demonstration of the tumors in the roentgenogram led to the diagnosis.

The tendency for the patient with pernicious anemia to develop a bulky or polypoid type of gastric tumor was notable. This corresponds well with the finding of a high incidence of polypi in such patients and with

the well known tendency for achlorhydria to occur in patients with benign polyps or polypoid types of gastric carcinoma.

The discovery, in patients with pernicious anemia, of so many small tumors of the stomach, both benign and malignant, indicates the possibilities of the roentgen examination of the stomach even as a survey method. During the study the positive errors in diagnosis, which had been exceedingly low before, showed a distinct increase, but the total results justified the increased risk. It is our opinion that only a thorough roentgen examination of the stomach, using fluoroscopy, spot films and routine roentgenograms, will achieve the results here reported.

While it is evident that the routine semiannual roentgen examination of the stomach in patients with pernicious anemia is a highly productive procedure, it does not penetrate very deeply into the problem of the early recognition of carcinoma of the stomach, since, at most, 5 per cent of the patients who develop cancer of the stomach will have pernicious anemia. The results achieved in this study, however, point the way toward a more general utilization of the roentgen examination of the stomach in larger groups of individuals who might be likely to develop carcinoma. For example, if all those with achlorhydria were examined routinely and repeatedly, a larger salvage might be accomplished. It may not be too bold to predict that eventually we may conduct survey examinations of the stomach as we now do of the lungs.

SUMMARY AND CONCLUSIONS

In a roentgen study of 211 pernicious anemia patients on whom examinations of the stomach were made on one or more occasions carcinoma of the stomach was found in 8 per cent and benign polyps in 7.1 per cent of the cases.

In an autopsy study, reported elsewhere, 12.3 per cent of patients with pernicious anemia were found also to have carcinoma of the stomach.

The data presented indicate clearly an etiologic rather than an accidental relationship between pernicious anemia and tumors of the stomach.

The routine roentgen examination of the stomachs of patients with pernicious anemia has proved to be a valuable procedure resulting in some salvage of cancer cases which might otherwise not have been obtained.

Cases were observed illustrating the rapid change from a benign polyp to a cancer, the presence of both benign and malignant tumors side by side, the absence of symptoms in the presence of large tumors, and the development from a small, barely detectable lesion to an extensive inoperable carcinoma.

ABSTRACT OF DISCUSSION

DR. HARRY M. WEBER, Rochester, Minn.: Pernicious anemia is a disease of the gastric mucous membrane plus a disorder of the hematologic and neurologic systems. Other findings are described pathologically in association with pernicious anemia, particularly the findings that are loosely described under the words "gastritis, atrophic and hypertrophic." We make attempts roentgenologically to distinguish a stomach that is affected with one of these conditions from the normal stomach. It is a difficult distinction to make in many instances. In the early stages of the inflammatory conditions that are found with pernicious anemia, just as in the early stages of the neoplastic changes that are found with pernicious anemia, the x-ray detection of these processes becomes difficult. The word "precancerous" probably is well used with regard to the stomach, as it is elsewhere in the gastrointestinal tract. Any polypoid lesion occurring anywhere in the gastrointestinal tract may be a potentially malignant lesion, and many of them are found to be so. All of them have to be considered so until microscopic examination proves them to be otherwise. I do not think we have the right to permit a patient, on the basis of our examinations, to believe that he has a benign lesion. Once the word "neoplasm" comes into the x-ray report, the malignant aspect of the neoplastic process has to be given primary consideration, and the patient has to have the benefit of histologic proof.

DR. PAUL SWENSON, New York: Drs. St. John, Harvey and I attempted a mass survey of the gastrointestinal tract particularly in the age group above 50 with no other idea than to study the statistical incidence of carcinoma. We studied 2,400 persons, repeating the examination in 1,000 of them. On the first thousand we used films as a check. After that we got a little more confident about our findings and did a rapid examination. We found 3 instances of carcinoma in persons who had never been to a doctor before for any gastrointestinal disorder. One of these cases was far advanced, the second a relatively early carcinoma and the third a lymphoblastoma. Our third case was such an early infiltration that we saw motor abnormalities alone, a spasm in apparently inflexible areas. We examined the abdomen and found what we thought was a normal stomach. Six months later the patient was back with a far advanced lesion. The indication is that sometimes by x-ray we can pick up a lesion which is infiltrating intramurally and yet feel normal to the fingers of the surgeon. Dr. Rigler's work is commendable, particularly his emphasis on the repeated examinations and watching for these supposed lesions to develop.

DR. P. RAMOS CASELLAS, San Juan, Puerto Rico: I have been practicing in Puerto Rico for the last five years, where the incidence of primary anemia is quite high. As a matter of fact, the incidence of all anemias is high there. The secondaries we attribute to dietetic deficiencies resulting from poverty. That may explain the fact that I have seen in Puerto Rico much more cancer of the gastrointestinal tract than I saw in twenty-five previous years in different sections of the United States.

DR. LEO G. RIGLER, Minneapolis: I wish to emphasize the fact, which Dr. Weber brought out, that polyps of the stomach are precancerous lesions, and in many instances it is impossible to determine definitely whether they are benign or malignant. The problem of how to handle the individual case is a difficult one. It is much harder to answer the surgeon's question about a specific case "Do you think I ought to resect this stomach?" than to make a general statement about the treatment of such lesions. The end result usually is that one must make up one's mind on the basis of the individual case rather than on any general rule. For instance, in a patient with a small gastric polyp, about 4 mm. in diameter, the program has been one of watchful waiting. In cases with larger tumors we have advocated resection, even though they appear to be perfectly benign. When one is examining patients who have no symptoms and is looking for small tumors, the percentage of positive errors is going to rise. This is a most unhappy consequence of this type of effort. Whereas prior to this time in our department the percentage of positive errors, that is, the diagnosis of a carcinoma when none is actually present, was almost nil, we now have several cases staring us in the face in which the surgeon has explored and found nothing. One more word about the matter of mass surveys in the examination of the stomach: A good many years ago we contemplated doing exactly what Drs. Swenson, St. John and Harvey did. When we investigated the statistical data on the incidence of carcinoma of the stomach in living persons we found that the largest number of cases of carcinoma which we would be likely to discover, even by restricting the examinations to men over the age of 45, would be about 3 per thousand. If one is to do a thousand examinations and do them carefully (and I think a study of the stomach properly done is a time consuming, painstaking and expensive procedure), the return of 3 per thousand is rather small. Perhaps we should undertake such a program, nevertheless, because the salvage of 1 case would well repay all that effort. Because, however, of the minimal return from the general group of cases, we picked pernicious anemia patients for this trial, because there we had hopes of getting a much more productive series. These hopes have been borne out.

EXPERIMENTS IN THE TREATMENT OF DEMENTIA PARALYTICA WITH PENICILLIN

CLARENCE A. NEYMANN, M.D.
GERT HEILBRUNN, M.D.
AND
G. P. YOUMANS, M.D.
CHICAGO

The modern treatment of dementia paralytica requires a long time and a great deal of effort. The newly developed method of administering massive doses of penicillin in early syphilis led us to believe that a similar rapid clinical result might be achieved in late syphilis of the central nervous system. We have not arrived at definite conclusions. We are presenting 5 cases. Primarily, we shall discuss the mode of treatment and the dosage; secondarily, the present clinical results.

ADMINISTRATION AND DOSAGE

It is known that no penicillin passes the hematoencephalic barrier after 10,000 or 20,000 Oxford units is injected intravenously or intramuscularly.[1]

In order to achieve therapeutic results, it seemed necessary to suffuse the brain and the meninges with penicillin. This might be possible by overcoming the barrier or by applying the drug directly to the surface of the brain.

In our first experiments, massive doses up to 1,000,000 Oxford units of the sodium salt of penicillin dissolved in 1,000 cc. of 5 per cent dextrose solution were given intravenously during a three hour interval. The spinal fluid specimen obtained immediately afterward did not reveal the presence of penicillin. The Oxford cup plate method [2] was used for purposes of assay. Another patient received a total dose of 3,100,000 units intramuscularly during an eight day period. This was repeated. The clinical picture and the spinal fluid findings remained unchanged. No penicillin was found in the spinal fluid.

A second attempt to breach the barrier was also of no avail. The patient received 10 cc. of a 20 per cent sodium dehydrocholate solution intravenously. This was followed by the intravenous injection of 300,000 units of penicillin dissolved in 1,000 cc. of 5 per cent dextrose solution containing, in addition, 20 cc. of a 20 per cent sodium dehydrocholate solution. This drug is credited with increasing the permeability of tissues and capillaries.[3] The dosage we used exceeds the customarily administered amount of sodium dihydrocholate. As already stated, no penicillin was found in the cerebrospinal fluid by biologic assay.

Next we treated a patient with penicillin and artificial fever. During the first febrile period 400,000 and then during the second period 500,000 units of the drug was administered by intravenous drip. The body temperature ranged near 105.8 F. for four hours. The fever cabinet described by Neymann and Holmquest [4] was used. In both instances the spinal fluid showed no trace of penicillin immediately after treatment. Therefore we concluded that the hematoencephalic barrier cannot be overwhelmed by massive or long continued or intramuscular or intravenous doses of penicillin. Neither does it yield to combined treatment of penicillin and bile salts nor to penicillin and artificial fever.

Finally, we experimented with subarachnoid administration. The dosage was of prime importance. No definite criteria existed. The direct intracisternal route was chosen. Single applications of 30,000 units were found to be tolerated without any untoward effects except occasional vomiting lasting a few hours after the injection. This dosage was administered daily to 3 patients for two weeks. The penicillin titers in the spinal fluid ranged between 0.7 and 11.6 units per cubic centimeter. No penicillin was present if more than thirty-six hours elapsed after the last injection. Simultaneous intramuscular injections of 350,000 units given daily for a week to the same patients failed to raise the spinal fluid penicillin titer. It did not prevent the disappearance of the drug from the spinal fluid after thirty-six hours.

Penicillin is toxic when it comes in direct contact with the surface of the brain. This toxicity may be due to impurities. The present commercial drug is either 40 or 25 per cent pure. The former seems less toxic than the latter. After repeated daily injections the patients complain of headache. Then they become tense. This state is followed by generalized muscular twitchings and finally by severe convulsions.

It is necessary to distinguish between acute and chronic reactions. A patient was given the very high dose of 100,000 units intracisternally. Three hours later he became tense. Generalized muscular twitchings and finally continuous convulsions with cyanosis followed. His life was saved by placing him in an oxygen tent and treating him with sodium amytal intravenously and spinal drainage. Similar reactions were observed after 50,000 and 40,000 units. This corresponds to the reactions described by Walker and Johnson [5] in experimental studies on animals.

The chronic effects of the drug are shown by meningeal irritation, rigidity of the neck and occasional positive Kernig and Brudzinski signs. Generally the latter signs were noted as after-effects of the convulsive states, but sometimes they followed prolonged administration of the drug without convulsive seizures. The spinal fluid showed an increase of cellular elements. Lymphocytes and polymorphonuclears as well as red blood corpuscles were found. The globulin and albumin increased correspondingly. Sometimes the temperature rose to 103 F., at others it dropped to 95 F. Two of our patients lapsed into a coma and died ten days after the last intracisternal injection.

CLINICAL AND SEROLOGIC RESULTS

Five patients suffering from chronic dementia paralytica were chosen for treatment. Mental symptoms in all of them had been present for from one to ten years. As stated, 2 of these died in a state of coma, from chronic penicillin encephalopathy. Another patient died as the result of exhaustion two weeks after treatment ceased. He showed no clinical improvement. Only 1 patient has improved.

Eight different modes of treatment were used, as shown in the table. The intramuscular, intravenous, intravenous with sodium dehydrocholate and intravenous with fever methods did not produce favorable clinical

The Commercial Solvents Corporation supplied penicillin and gave help and cooperation.

results. After intrathecal injections the serologic reaction changed in 2 of the cases, becoming practically negative. The colloidal gold reaction changed from a paretic to a negative curve. The cell count after the initial rise decreased to normal and in 1 patient the spinal fluid Wassermann reaction became negative. Both of the patients are alive. One remains as demented as he was in the beginning; the other is decidedly improved.

The blood Wassermann reaction of all 5 patients remained positive.

In order to give a better insight into the method of treatment, we will append the history of 1 patient:

M. F., a woman aged 42, was reported as having been restless and overanxious for the past four years. In July 1944 she became confused and unable to recognize people. Consequently she was hospitalized. The patient was treated with artificial fever and chemotherapy before she was admitted to the Chicago State Hospital. A day before penicillin treatment, the examination disclosed pupils fixed to light and in accommodation, exaggerated knee and ankle jerks, shuffling and staggering gait, partial disorientation, pronounced confusion, irrelevant and incoherent speech and positive blood and spinal fluid findings.

After one intracisternal injection of 20,000 units, the colloidal gold curve showed a normal reaction, 0000012100. Another two injections of 20,000 units each and one injection of 30,000 units produced a decided change in the patient's mental condition. Her stream of talk became much more relevant and coherent.

Modes of Treatment

1. Intramuscular.
2. Intravenous.
3. Intravenous with sodium dehydrocholate.
4. Intravenous with fever.
5. Intracisternal alone.
6. Intracisternal and intramuscular.
7. Intracisternal plus artificial fever plus intravenous.
8. Intracisternal plus intramuscular plus phenarsone sulfoxylate

This amelioration of mental symptoms became more pronounced during the next three weeks; during this time the patient received another course of fourteen intracisternal injections of 30,000 units each. The last ten were given daily. The colloidal gold curve remained flat during this period. There was no reversal of the 4 plus Wassermann reaction. An additional course of eleven intracisternal injections of 30,000 units each, given daily in conjunction with 350,000 units intramuscularly, rendered the spinal fluid Wassermann reaction negative.

At the conclusion of the penicillin treatment the patient's mental condition was approximately normal except for a mild euphoria. Her gait improved, but the reflexes were unchanged. Since this time her spinal fluid Wassermann reaction has shown a tendency to return to positive. She is being treated with tryparsamide and bismuth.

CONCLUSIONS

At present we conclude that:

1. The intravenous and intramuscular injection of penicillin is ineffective because the hematoencephalic barrier cannot be breached.

2. The intracisternal route is dangerous if more than 30,000 Oxford units is injected.

3. The daily injection of this dose prolonged for more than five days is also hazardous.

4. The chronic pachymeningitis and leptomeningitis are probably favorably influenced by the drug.

5. The syphilitic involvement of the parenchyma in the depths of the cortex probably remains unchanged.

It is our intention to follow up this study by the use of pure crystalline penicillin and the simultaneous treatment with phenarsone sulfoxylate, tryparsamide and heavy metals.

THE DIAGNOSIS OF ACUTE SURGICAL DISEASES OF FEMALE PELVIS AND LOWER ABDOMEN

LIEUTENANT COLONEL WILLIAM J. CARRINGTON
MEDICAL CORPS, ARMY OF THE UNITED STATES

In the hope of emending the accuracy of preoperative diagnoses in acute surgical lesions of the pelvis and abdomen in women, at least in the Atlantic City Hospital, a study of inaccuracies and errors in that institution was begun in 1936. At the end of five years a preliminary report was made to the Medical Society of New Jersey. This was to be compared with anticipated improvement during the next five year period. But the plan was interrupted by the war. This paper is based on the results of the original five year period together with those of the following year. After the war the apocryphal results will be compared with those of a similar period. Improvement is a consummation devoutly to be wished.

Diagnosis is based on the recognition of signs and symptoms. It is often necessary to wait for them to develop before an exact diagnosis can be made. In abdominal catastrophes one cannot wait. Some mistakes are pardonable. The unpardonable sin is to wait until error is impossible. That would mean the sacrifice of human life on the altar of statistical perfection.

Sudden intolerable abdominal pain accompanied by unmistakable rigidity is a surgical green light regardless of exact diagnosis. Wangensteen's decompression and parenteral fluids give extra time for greater accuracy, but, even with these, delay may spell disaster.

It is embarrassing to operate for appendicitis and find the mesenteric adenitis of what turns out to be measles. What a booby trap it is! Once in a while pain, McBurney tenderness, rigidity, fever and leukocytosis antedate the rash. When the surgeon is called to see such a case he knows that appendicitis in childhood demands early operation because nature makes no effort to wall off the infection. He operates in good faith. Give him sympathy. He will blush for himself.

Many authors state that females are less susceptible to appendicitis than males in the ratio of 2 to 3 or even 2 to 5. Atlantic City Hospital records would seem to confirm this. There are fewer cases in women's surgery than in men's surgery; but if those treated in the gynecologic department are added there is little difference in the two sexes.

A generation ago surgeons were taught that the ovarian artery had an appendicular branch which furnished extra blood and hence relative immunity to the female. Today modern textbooks state that the blood supply of the appendix is the same in the two sexes. So much for the history. What about the clinical findings?

CLINICAL OBSERVATIONS

1. With regard to posture, if the patient lies on either side there is no peritonitis. If she lies with her right thigh flexed she may have phlebitis, but she is more apt to have appendicitis. This position does not relieve the pain of adnexitis or of lesions of the urinary tract. It is therefore of real diagnostic value. In perforation of a viscus the patient lies immobile, stiff as a mummy. In ruptured ectopic pregnancy she is restless, tossing from side to side, begging for water. In streptococcic

Read before the Section on Miscellaneous Topics, Sessions for the General Practitioner, at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 15, 1944.

cellulitis she is bright, flushed and talkative. Her euphoria may confuse the unwary.

2. Temperature, pulse and respirations are not very helpful. In appendicitis and adnexitis there is moderate elevation. In cellulitis the temperature is pump handle. In pyelitis, pyelonephritis and pyonephrosis there may be also wide fluctuations. When an ectopic pregnancy ruptures, the temperature drops. Later there is fever due to absorption of fibrin ferment. A lower abdominal emergency without fever or leukocytosis is apt to be the sudden twist of the pedicle of a solid or cystic tumor. If torsion is neglected, particularly if the cyst is a dermoid, peritonitis quickly follows, with fever and leukocytosis.

The pulse varies with the amount of shock and hemorrhage. It is more rapid in cellulitis. In perforation there are pallid face, staring eyes and sweated brow, but the pulse is surprisingly tranquil.

Respirations are accelerated in all abdominal catastrophes, but air hunger is the distress signal of internal bleeding.

3. The localization of tenderness is of the utmost importance. The patient will point out the area of greatest tenderness. In appendicitis it finally settles near McBurney's point. In salpingitis it is lower and is apt to be on both sides. Morris's points have not been very helpful. In urinary tract lesions the tenderness is over the bladder or flanks. In pelvic cellulitis there is little or no tenderness unless peritonitis develops.

In pregnancy the ovaries, tubes and appendix are lifted up. While pregnancy does not appear to increase the liability of primary attacks of appendicitis, recurrences are all too common. Increased blood supply, constipation and elevation of the cecum with pull on old adhesions combine to relight previous trouble. Perforation and abscess are much more dangerous in pregnant women. Abortion or premature labor is the rule, and when the uterus empties itself it pulls away and disseminates the infection.

4. Cutaneous hyperesthesia, tested by pinching the skin, may reveal hypersensitiveness over the appendix. The sensory nerves of the skin in that area come from the same segment of the cord supplying the appendix with its sympathetic nerve fibers. One should not place too much reliance on this sign, because it requires a subjective response.

5. Muscle spasm is of prime importance but can be elicited only by gentle manipulation. The intensity of rigidity depends on the proximity of the appendix to the parietal peritoneum. In salpingitis, rigidity is less and bilateral because heavy inflamed tubes prolapse in the cul-de-sac. In ruptured ectopic pregnancy, rigidity is generalized. In pelvic cellulitis and torsion there is no rigidity until peritonitis sets in.

Muscle spasm is not pronounced in typhoid perforation, because this accident occurs in the third week. By this time Zenker's degeneration in a fifth column sort of way has rendered the rectus muscle incapable of resistance.

Rebound tenderness indicates peritoneal involvement, but it excites undue pain and apprehension and may actually spread infection.

6. A readily palpable, rounded mass low in an acutely inflamed abdomen suggests a solid or cystic tumor with a twisted pedicle. In early appendicitis the omentum wraps itself around the appendix like a scarf around a sore throat, to form a tender, indefinite mass. An appendical abscess which takes some days to form may be felt in the lower right quadrant, in the flank or in the pelvis. I once opened, in my office, what appeared to be a large fluctuating femoral gland abscess which pointed below Poupart's ligament. Imagine my surprise when a gangrenous appendix floated out in the pus.

7. Abdominal auscultation is too often neglected. In obstruction, peristalsis is tumultuous, and long gurgling, guttural rolls are characteristic. In peritonitis there is stony and ominous silence, broken now and then by a reverberating drip like water falling in the silence of a resonant cave. In hemorrhage there is said to be crepitus.

8. A distinguished author suggests that "if the history and abdominal findings are inconclusive, a careful yet gentle pelvic examination assumes great importance." Let me emphasize that a medical officer in the Army had better not let General Kirk catch him if he ever fails to do a rectopelvic examination in any abdominal case, high up or low down. In reviewing mistakes made in the 1,932 cases reviewed in writing this paper the most vivid impression gained was that more errors were committed by neglecting the pelvic examination than by omitting all other diagnostic procedures combined. Let us therefore without fail do pelvic examinations through the vagina or through the rectum not only when the history and abdominal findings appear to be inconclusive but in all cases.

An intact hymen rules out salpingitis almost certainly, but a palpable Bartholin's gland, purulent skenitis or urethral discharge is strong circumstantial evidence, and cervicitis in a nullipara is more than gossip.

Tenderness of the adnexa is best demonstrated by a maneuver not described in textbooks. The examining finger pushes the cervix to the left. The uterus acts as a lever and puts the right adnexa on the stretch.

Female Patients with Pelvic and Lower Abdominal Emergencies at the Atlantic City Hospital, Jan. 1, 1936 to Dec. 31, 1941

Final Diagnosis	Total	Tentative Diagnosis Correct	Accuracy
Acute appendicitis, including purulent appendicitis, abscess, gangrene, perforation and peritonitis	959	778	80%
Acute adnexitis, including hot tubes, acute salpingitis, pyosalpinx, tubo-ovarian abscess and acute gonorrheal peritonitis	505	392	77%
Acute lesions of the urinary tract, including cystitis, interstitial cystitis, pyelitis, stones, pyelonephritis, pyonephrosis, ptosis of the kidney and stricture of the ureter	176	158	90%
Endometriosis	77	12	16%
Hernia, strangulated or incarcerated; two of these were intra-abdominal	53	50	96%
Ruptured cysts, graafian follicle, corpus luteum, dermoid, pseudomucinous and papillary cysts	51	31	60%
Ruptured ectopic pregnancy, including ruptured tubal pregnancy and tubal abortion	49	28	57%
Torsion of tumors, solid or cystic	15	7	47%
Pelvic cellulitis, including postabortive and early and late puerperal sepsis; the two missed diagnoses were in women who denied abortion	14	12	86%
Mesenteric adenitis due to measles, scarlet fever, "glandular fever"	8	0	0%
Tuberculous peritonitis	9	2	22%
Mittelschmerz	8	0	0%
Diverticulitis	7	2	28%
Torsion of omentum	4	0	0%
Mesenteric thrombosis	3	0	0%
Regional ileitis	2	0	0%
Ruptured typhoid ulcer	1	0	0%

Tenderness elicited by this simple maneuver marks the spot in the right broad ligament.

Induration of acute salpingitis may be demonstrable only when the patient is relaxed. With the patient and the operating room prepared for appendectomy, if the relaxation of the anesthesia permits a correct diagnosis it is sound judgment to postpone operation until the tube "cools off."

Pelvic examination is important in suspected ectopic pregnancy. The uterus is enlarged, the cervix is soft and there is slight bleeding. The pregnant tube "rides high" and forward, whereas pus tubes are heavy and fall back into the depths of the cul-de-sac.

Large pelvic abscesses of recent origin are almost certainly appendical. These collections of pus cannot be palpated through the abdomen but only through the vagina or rectum. They should be drained through the cul-de-sac, because they are closed off above by coils of intestine.

A small pelvic abscess may be appendical where the appendix hangs over the brim of the pelvis. But this abscess is high, whereas a tubo-ovarian abscess is low in the cul-de-sac. Moreover, tubal masses are sausage shaped and bilateral. Unilateral pyosalpinx is due to pyogenic cocci and not to gonococci.

Appendicitis secondary to tubo-ovarian disease is not alarming because the inflammation involves the peritoneal coat and not the lumen of the appendix. It is safe to allow the case to subside even though it is certain that the appendix is involved.

If pelvic examination reveals a retroflexed uterus with "frozen" adnexa and a "shotty feel" along the uterine ligaments, the diagnosis of endometriosis is probable. If speculum examination reveals small chocolate cysts or their little stellate scars in the vault of the vagina, endometriosis is certain.

The pelvic mass may be a solid or cystic tumor. Torsion of such a tumor is one of the causes of acute conditions in the lower part of the abdomen. Cysts that twist are of medium size. Sometimes the twisted pedicle can be palpated. If such a patient develops early peritonitis one should suspect a dermoid cyst, because its contents are particularly irritating.

Crepitus means clots of blood and hence ruptured ectopic pregnancy or ruptured cysts with internal bleeding.

LABORATORY AID

The help that urinalysis has to offer is so well known that comment is unnecessary. A single specimen may show neither blood nor pus if the ureter is temporarily blocked in pyelitis, pyelonephritis or pyonephrosis. On the other hand, blood and pus may appear in the urine when there is no real urinary tract infection but when there is extension from a retrocecal appendix or a tubo-ovarian abscess.

The leukocyte picture depends on the nature of the infection, the tissue involved and the factors that promote absorption. Other things being equal, staphylococci, gonococci and Escherichia coli excite leukocytosis less than streptococci. The tissue invaded influences the count. Thus tuberculosis and typhoid which invade the lymphoid tissue show a low count, whereas infection of the peritoneum causes enormous polymorphonuclear increase. Moreover, a small amount of pus under pressure, as an abscess confined to the appendix, will produce a higher count than a large abscess that is draining.

In bleeding ectopic pregnancy, leukocytes continue to rise but drop quickly when hemorrhage ceases.

With the history and physical signs of appendicitis and leukocytosis of 15,000 the appendix may be expected to be merely inflamed. When the count approaches 20,000 there is usually pus; but do not put all your money on it even if you know who makes the blood count. If there are colicky pains and a count of less than 12,000 there may be obstructive appendicitis followed by rupture. This sequence of events causes 90 per cent of appendical deaths. In this group an increasing shift to the left is an urgent indication for early operation. Finally it should be remembered that leukocytosis occurs in uremia, acidosis, intestinal obstruction, coronary thrombosis and even alcoholism.

In ruptured ectopic pregnancy the first blood count may show an actual increase in red cells due to the blood concentration of shock. The sphygmomanometer is a more reliable witness. However, evidences of anemia soon appear. Because cells regenerate more rapidly than hemoglobin, ghost cells are seen and the color index is low.

Hemoglobin is not an accurate indicator of internal hemorrhage. It does not reach its highest level until forty-eight to seventy-two hours of bleeding. That is why a high level of hemoglobin does not rule out ruptured ectopic pregnancy. Falling blood pressure is more valuable than falling hemoglobin in the diagnosis of hidden hemorrhage. According to Farrar, a complete blood count every two hours will indicate when bleeding starts and stops, and this observation has been confirmed time over and again.

The sedimentation rate varies with extent and severity of the infection. It tells more than leukocytosis about the end stages of disease. When the rate is rapid in pelvic inflammatory disease, operation is risky and followed by stormy convalescence. The rate in appendicitis is slower than in pelvic inflammatory disease or in pelvic cellulitis. In differentiating between ectopic pregnancy and pelvic inflammation a slow rate points toward ectopic pregnancy. However, sedimentation is valueless as a diagnostic aid after the third month of pregnancy, because it is always rapid from the third month until two weeks after delivery even in the absence of inflammation.

Blood cultures, the Friedman test and the complement fixation test for gonorrhea do not help solve acute diagnostic problems. Special diagnostic procedures are rarely useful. These are cystoscopy, x-ray examination and the Rubin test. The Bastedo procedure of eliciting pain and McBurney tenderness by inflating the colon with air pumped in through a rectal tube may be helpful in diagnosing that will of the wisp chronic appendicitis, but it has no place in acute appendicitis.

The cases of regional ileitis were mistaken for acute appendicitis. The abdomen was closed when the regional thickening and adenopathy were discovered. Little is known of the etiology of regional ileitis. Out of the mist and fog which surround this much discussed condition two facts emerge crystal clear. Do not operate in the acute stage and, if operation is performed because acute appendicitis is suspected, do not remove a normal appendix to salve one's conscience. Get out and close up.

It is embarrassing to miss the diagnosis in ruptured ectopic pregnancy. Fifty-seven per cent of accuracy is not too good. In typical cases the ambulance driver can take one look and do better than that. But not all are typical. Some years ago I had a series of ectopic pregnancies with regular menstruation and moderate

hemorrhage which promptly ceased spontaneously. I missed so many that I was tempted to write on the preoperative chart of doubtful cases the exact opposite of what I really thought. It would have been almost as accurate.

THE CASE HISTORY

The impression from a review of these 1,932 cases is inescapable that many mistakes could have been avoided if clues in the histories had been followed. Sign-posts which pointed the way were disregarded.

If the onset occurs at the time of menstruation, the reproductive organs may or may not be the site of the lesion. Appendicitis, acute or chronic, occurs more frequently when there is pelvic congestion. There is delayed or missed menstruation in 85 per cent of ectopic pregnancies. Fever and chills following childbirth or abortion suggest pelvic cellulitis. Dysmenorrhea which begins late in menstrual life in the third decade, which becomes more distressing each month, which is seen in women in the upper walks of life who have used contraceptives and vaginal tampons is usually due to endometriosis. Had these facts been elicited by careful histories, we should not have missed 65 out of 77 cases.

The sequence of events is important. If there are sudden pain in the periumbilical region shifting to the right lower quadrant, nausea and vomiting, tenderness, rigidity, fever and leukocytosis in that order, the diagnosis could hardly be plainer if flashed in neon lights. The trouble is that many things break up the sequence, such as pelvic appendix or failure of the cecum to rotate. However, nausea and vomiting are the clues to follow. The first symptom of appendicitis is pain, always pain, never anything else. If some other symptom is first, the appendix is blameless. The site and severity of the pain are inconstant, but pain comes first. A history of "cold in the bladder," leukorrhea or bartholinitis directs attention to the adnexa. If gastrointestinal symptoms are absent, if the pain is deep in the pelvis and constant rather than paroxysmal, the diagnosis of adnexitis is fairly certain.

In appendicitis and strangulated hernia the constipation is more absolute, but 15 per cent of appendicitis patients have diarrhea, and most of these die. If food, fluid or physic is given a patient with appendicitis, the pain becomes intolerable and recovery difficult and doubtful. Appendicitis is bad enough, but its axis partners—food, fluid and physic—are worse. They bring peristalsis, perforation and peritonitis.

Colpotomy is useful in ectopic pregnancy with slow bleeding. I have no desire to possess a peritoneoscope, having seen it used elsewhere. It is brutal and futile. The shock of inflating the peritoneal cavity with air and the danger of perforating the intestine are too great and the keyhole view is unsatisfactory even for the most ardent peeping Tom.

SUMMARY

During a six year period 1,932 women with surgical emergencies of the pelvis and lower part of the abdomen were admitted to the Atlantic City Hospital, a class A institution with a closed surgical staff in a community of 66,000. Accurate preoperative diagnoses were made in 71 per cent of these women. In 29 per cent the diagnosis was correct only in part or wholly in error. In a certain number immediate operation was necessary to save life. There was no time for refined differentiation. By and large errors were due to incomplete histories and the failure to utilize, not gadgets, but the tactus eruditus.

Clinical Notes, Suggestions and New Instruments

DERMATITIS OF THE LIDS FROM PENICILLIN EYE DROPS

ELIAS SELINGER, M.D., CHICAGO

Various untoward reactions from penicillin have been reported in the literature. Urticaria has been observed from the systemic administration of the drug and skin rashes from direct contact with the substance and the solution of penicillin. In some instances the reaction was thought to be the result of contaminants rather than of the drug itself.

Binkley and Brockmole,[1] as well as Silvers,[2] describe a case of dermatitis of other parts of the body associated with involvement of the lids. The only case so far described, to my knowledge, in which a dermatitis of the lids followed the instillation of penicillin solution into the conjunctival sac is that of Keyes.[3] In that case one drop of 1:1,000 penicillin sodium solution was instilled into the conjunctival sac at hourly intervals for four doses. Before the last drop was administered the conjunctivas and lids became red and swollen. The redness and swelling of the lids increased considerably and the conjunctivas became quite congested. In addition to this the mucous membranes of the nose and throat became dry, painful and glossy. The patient also developed a temperature of 100 F. and complained of general malaise. Patch tests were negative and the penicillin used in this case gave negative results when used on another patient and on a rabbit. The patient gave a history of sensitivity to a number of substances.

The subject of the present report is a white man aged 53 who had been receiving treatment for a bilateral chronic conjunctivitis for about a year. Cultures from the conjunctival sacs were negative. Various drugs, including sulfonamides and tyrothricin, failed to clear up the conjunctivitis.

On March 24, 1945 a solution of penicillin sodium, 250 Oxford units per cubic centimeter in isotonic solution of sodium chloride, was prescribed, with instruction to instil one drop in each eye every two hours. The patient used this solution for four days, when he returned to the office because there was no improvement in the conjunctivitis. He thought that a more concentrated solution might be more effective. Although at that time the skin of the upper lids seemed slightly edematous and somewhat shiny in appearance, this was not accepted as an early sign of a contact dermatitis as it would have been if other medication had been used. A solution containing 500 Oxford units per cubic centimeter was prescribed. The following day the patient returned to the office with a typical picture of a contact dermatitis. The skin of the lower lids was thickened, red and shiny in appearance. The redness of the lids was particularly pronounced along the side of the nose where the excess of the solution had trickled down over the cheeks. The skin of the upper lids, especially near the inner canthi, was edematous but not red. The conjunctivas showed no reaction, and the corneas, examined with a slit lamp, were also free from reaction. A patch test gave negative results. No history of urticaria, hay fever or other allergic manifestations could be elicited. The dermatitis cleared up five days after penicillin was discontinued.

The noteworthy features of this case are the absence of any conjunctival irritation in spite of the rather pronounced dermatitis of the lids and the occurrence of the dermatitis in an individual apparently not subject to allergic disturbances.

Incidentally the results of penicillin therapy in 3 cases of acute and in 9 cases of chronic catarrhal conjunctivitis were no better than those with the older therapeutic agents.

104 South Michigan Avenue.

Since this case report was submitted for publication, the writer has had a second case of penicillin dermatitis from topical application of penicillin solution.

CERVICOFACIAL ACTINOMYCOSIS SUCCESSFULLY TREATED BY PENICILLIN WITHOUT SURGICAL DRAINAGE

GLENN G. HENDRICKSON, M.D., AND EDWIN P. LEHMAN, M.D.
CHARLOTTESVILLE, VA.

Two cases of proved cervicofacial actinomycosis treated successfully by penicillin without the employment of surgical drainage are herewith presented.

CASE 1.—A housewife aged 27, admitted to the University Hospital July 28, 1944, had begun six weeks previously to have toothache, limitation of motion of the jaw and swelling in the region of the left lower molars. A week later spontaneous drainage into the mouth of what was apparently an alveolar abscess occurred, with subsequent temporary slight diminution in the swelling. Roentgenograms on July 17 showed caries of the crowns of the second and third left lower molars and an abscess around the root of the third. Two days later these teeth were extracted. Hot compresses were used, but there was no improvement in either the size of the mass or the motion of the mandible.

On admission the temperature was 37.5 C. (99.6 F.). Over the angle of the left mandible was an ovoid mass measuring 7 by 6.5 by 3 cm. The overlying skin was a little red and there was increased heat and tenderness. The mass was uniformly firm and seemingly attached to the mandible. The submaxillary and anterior cervical lymph nodes were swollen and tender. With difficulty the mouth was opened 1 cm. to expose dirty and carious teeth, and a small sinus tract at the site of the recently extracted third molar.

The white blood cell count was 10,000. The blood Wassermann reaction was negative. X-ray examination revealed no abnormalities in the mandible. Three cc. of pus aspirated through the cheek contained large numbers of sulfur granules. Wet preparations and gram stains were positive for actinomycetes, and Actinomyces bovis was cultured from the material.

One hundred thousand Oxford units of penicillin was given every twenty-four hours by continuous 1,500 cc. intravenous drip of 5 per cent glucose in isotonic solution of sodium chloride for a total of 460,000 units in four and one-half days. Early in the course of treatment 10,000 units in 2 cc. of isotonic solution of sodium chloride was twice injected directly into the mass after a small quantity of pus had been aspirated. Following the intravenous medication 120,000 units of penicillin was given daily by intramuscular injections of 15,000 units every three hours for a total of 660,000 units. The dose was then increased to 160,000 units in twenty-four hours until 860,000 units was given at this rate. The course of treatment lasted sixteen days, and a total of 2,000,000 units of penicillin was administered. Hot wet compresses were applied to the jaw during most of this time.

Within forty-eight hours after the initial dose of penicillin there was a decrease in the local tenderness and induration. By the fourth day the swelling was noticeably smaller, and on the ninth day the mass measured 5 by 4.5 cm. The highest temperature attained was 38 C. (100.4 F.) and after the sixth day the patient was afebrile. At discharge on the eighteenth day a localized area of nontender induration measuring 3 by 2 cm. and a minimal limitation of motion of the mandible remained.

Three weeks after leaving the hospital a firm anterior cervical lymph node persisted below the angle of the jaw. The patient was seen six months later. She had remained asymptomatic, and examination revealed no evidence of previous disease.

CASE 2.—A white man, aged 63, a farmer, admitted to the hospital Sept. 18, 1944, had had an aching left lower molar tooth extracted seven weeks previously, and shortly afterward pain, swelling and limitation of motion of the jaw had developed. He was intensively treated with sulfonamides by his local physician. Dental films on September 15 showed at the site of extraction of the lower left third molar a small sequestrum lying just above the alveolar margin with a small area of soft tissue density around it. The day before entering the hospital the abscess drained spontaneously through a small opening in the neck. During the illness he had lost 20 pounds (9 Kg.).

On admission the patient's temperature was 37 C. (98.6 F.). Just below the angle of the left mandible was a firm fixed ovoid mass measuring 6 by 6 by 2.5 cm. In the central portion was a small opening from which a few drops of sanguinopurulent material drained. There was no increase in heat, but moderate tenderness was present. Dirty and carious teeth were seen in front, but the mouth could not be opened enough to view the molar regions.

The white blood cell count was 5,200. The blood Wassermann reaction was negative. Pus expressed from the sinus contained sulfur granules of Actinomyces.[1]

One hundred thousand Oxford units of penicillin was given every twenty-four hours by continuous 1,500 cc. intravenous drip of isotonic solution of sodium chloride for a total of 400,000 units in four days. Thereafter 120,000 units was given daily by intramuscular administration of 15,000 units every three hours for a total of 600,000 units. The dosage was then decreased to 80,000 units in twenty-four hours, and 500,000 units was given at this rate. The course of treatment lasted fifteen days, and a total of 1,500,000 units of penicillin was administered. The patient also received 6 Gm. of sulfadiazine daily during the first six days of treatment.

Four days after the initial dose of penicillin the mass was less indurated and tender. By the end of the second week the drainage had ceased, and the remaining nontender mass measured 2 by 2 cm.

A month after leaving the hospital the localized induration persisted almost unchanged. However, at the end of four months the patient was asymptomatic and the only evidence of previous disease was a well healed scar less than 0.5 cm. in diameter beneath the angle of the mandible.

COMMENT

Actinomycosis is a disease which has no uniformly satisfactory method of treatment. Inconsistent results with penicillin have been recorded in brief notes from various workers.[2] Garrod[3] found that different strains of Actinomyces differ greatly in their sensitivity to penicillin and demonstrated an apparent correlation in 4 cases between the in vitro and in vivo reaction to the drug.

The history of the treatment of actinomycosis includes the employment of substances which have been believed from time to time to have a specific action on the actinomycete. The most widely used, before the availability of the sulfonamides and penicillin, have been the iodides and thymol. Whatever drug is used, however, it has been the consistent opinion of surgeons that no beneficial results are to be expected in the absence of wide surgical drainage.[4] In cases cured by these methods, prolonged healing of open wounds and conspicuous scars are the uniform accompaniment.

These 2 cases are presented to indicate that certainly in some instances actinomycosis may yield to penicillin without the necessity for painful and deforming surgical procedure. We believe that the diagnosis of actinomycosis should be attempted by aspiration of fluctuant areas in a suspected lesion rather than by open drainage, since there is a possibility that the latter procedure may be unnecessary. It is suggested that all proved cases of actinomycosis receive intensive penicillin therapy without immediate surgical drainage. If the organism is found insensitive to penicillin, either by laboratory demonstration or by clinical response or both, then and only then is the standard surgical attack justified. Delay in surgical drainage for the clinical test of penicillin response should not alter the prognosis to any important degree, since the infection is of slow development in any event.

Council on Foods and Nutrition

SPECIAL ARTICLE

This is the seventh of a series of articles discussing the significance of protein nutrition in health and disease. This material was prepared by the authors at the request of the Council and has been authorized for publication.

GEORGE K. ANDERSON, M.D., *Secretary.*

THE CLINICAL DETECTION OF PROTEIN DEFICIENCY

COLONEL JOHN B. YOUMANS
MEDICAL CORPS, ARMY OF THE UNITED STATES

Protein deficiency occurs from a variety of causes: as a result of a deficient intake, a failure of absorption or utilization, abnormal destruction, or an abnormal loss from the body as in burns or nephrosis. It can occur in an acute or a subacute form, as in hemorrhage or burns, or as a chronic disease. Diagnosis of the deficiency will depend somewhat on the cause of the deficiency, mainly in respect to the evidence contributed by the history and physical findings. For the most part, however, the diagnosis of all forms will be similar to that of the nutritional deficiency type, which will serve as the example in most of the present discussion.

When considering the diagnosis of protein deficiency, distinction must be made between a deficiency of protein in the diet and the physical state of a deficiency of protein in the body. They are not the same and, although a history of a dietary deficiency may be helpful in the diagnosis of protein deficiency disease, unless the dietary has been inadequate greatly enough and long enough to exhaust the reserve stores such inadequacy is not of itself sufficient for a diagnosis of protein deficiency.

Distinction must also be made between a deficiency of protein as protein and a deficiency of amino acids. Some ten of the many amino acids found in protein have essential specific functions yet cannot be synthesized by the body. Hence there may occur specific amino acid deficiencies. A deficiency of protein is often accompanied by a deficiency of specific amino acids, but there can be and often is a deficiency of protein as protein distinct from any deficiency of specific amino acids.

Finally a distinction is to be made between the diagnosis of protein deficiency in individuals and in populations, because the methods which are suitable in the one instance may not be satisfactory in the other.

Aside from the diet record the history in the usual case of nutritional protein deficiency is of relatively little assistance except for the symptoms of edema, a rather late manifestation of the deficiency. In cases of protein deficiency resulting from failure of absorption or utilization, abnormal destruction or loss from the body as in nephrosis or burns, the history and symptoms of the conditions causing the deficiency will be suggestive and helpful.

The history and study of the diet, though not diagnostic, is very useful, and knowledge of a possibly inadequate intake should always suggest that protein deficiency exists. Inquiry into the diet should be made with some care because even small deficits existing over a long time can cause a deficiency state in the end. In many cases it will be advisable to obtain a record of the amounts and kinds of food eaten over a period of a week or more. From this the dietary intake can be calculated and an estimate made of the probable intake over a longer period. The calculated intake should be compared with known requirements of different individuals under various conditions. For example, children require relatively more protein than adults, because of growth. Certain illness and injuries, for example burns, are now known to increase the requirements greatly.

Of almost greater importance in some cases than the actual amounts of protein is the caloric intake. This is because protein is burned for heat (calories) in the absence of sufficient fat and carbohydrates to supply energy requirements. Actually, healthy adults, if given sufficient fat and carbohydrates to supply all energy needs, require only small amounts of protein.[1] With the usual dietary and its excess of protein, some protein is burned for heat. However, when the amount of protein in the diet is near minimal the use of some of it for fuel may make the supply inadequate, and amounts which appear adequate may actually be insufficient. Actually most diets deficient in protein are only relatively deficient.

Finally, inquiry should be made as to the biologic quality of the protein. So-called first class protein, animal protein, is more complete and richer in essential amino acids than most other proteins. Though an adequate intake of protein can be secured with vegetable protein, it ordinarily requires a greater variety of food and larger amounts. The production of a negative nitrogen balance, by a deficiency of essential amino acids, despite the intake of adequate amounts of protein per se, emphasizes the necessity for a sufficient supply of first class protein.

Although a deficiency of protein interferes with growth and development, strength and energy, the production of immune bodies and such physiologic functions as pregnancy and lactation, those disturbances have so many causes and are the result of so many factors that it is difficult clinically to identify them with a deficiency of protein. Similarly, with the exception of disturbances in growth of hair and in fertility as possible manifestations of amino acid deficiencies (cystine and arginine), specific or even suggestive symptoms of amino acid deficiency are lacking.

The edema, although not the earliest result of protein deficiency, in our present state of knowledge is about the first clinical sign of the deficiency. One of the characteristics of the edema is its lack of association with symptoms suggesting other causes of edema, notably heart and kidney disease. Although in severe cases of nutritional (protein deficiency) edema there may be a history of shortness of breath and palpitation, these are usually lacking. The edema is strikingly dependent on posture, confined to or greatest in dependent parts and, especially in the mild or early stages, shifting from part to part with posture, present in the hands and face in the morning and in the legs at night. In the mild cases, because it is greatly affected by other secondary factors such as environmental temperature and salt and water intake, it is inconstant and may appear and disappear. It is usually painless, bilateral though perhaps greater on one side, and usually develops gradually and

1. The usual diet, however, should contain liberal amounts of protein.

insidiously, though occasionally the onset is sudden, following unusual exercise or excessive salt and fluid intake. With the more acute onset there may be a tight feeling in the legs and slight to moderate pain and tenderness.

There may be noted a rather sudden increase in weight, often with weakness and lassitude. Loss of weight is usually masked by the edema. Polyuria, especially nocturia, may occur, but there may be some oliguria at the onset of the edema. In simple undernutrition cases mild mental depression is common. When accompanied by other disease the symptoms of the latter are apt to overshadow those of the protein deficiency, and uncomplicated cases often show few symptoms. Only in severe protein deficiency is there an accompanying ascites and hydrothorax.

The same diagnostic limitations that affect the history apply to the physical examination. Almost the only characteristic or sufficiently significant finding is the edema, and, in advanced cases, fluid in the serous cavities. This edema, as already pointed out, differs in no essential way from some other forms of edema and must be distinguished from them on the basis of other evidence. It is, however, a positive finding of importance, and it must be remembered that the edema of protein deficiency may and often does accompany and complicate other forms of edema.

The dropsy is usually of the soft, pitting variety, rarely becoming hard and indurated unless complicated by other kinds of edema. Ordinarily it is greatest in the feet and legs, where it is usually noted first, or as a slight swelling of the face and hands, to which it shifts during recumbency to be noted on arising. Occasionally, when developing suddenly, it may be accompanied by some redness and tenderness. As it increases in severity it extends higher, becomes greater and in the most severe cases becomes a true anasarca. In the milder cases disappearing completely with a few days of bed rest, when more severe it persists or even develops with the patient in this position.

Other physical findings either are the secondary manifestations of the edema or are the result of associated abnormalities, which often accompany the protein deficiency and hypoproteinemia. Pallor commonly present is caused by the overlying edema, accompanies a decreased blood volume or reflects an actual anemia, which may be related to the protein deficiency or to other causes. Actual anemia is not common in uncomplicated cases, though hemoconcentration may mask an anemia of mild degree. Loss of weight is often obscured by the retention of water, as is muscle atrophy, both being revealed in their true aspect only when diuresis occurs. Dyspnea and tachycardia, of effort, not of posture, reflect several causes—the physical effect of edema and fluid in serous cavities, the lessened blood volume and the actual atrophy and loss of substance of muscles and that muscular organ the heart. Weakness of skeletal muscles has the same causes. Bradycardia at rest is observed in severer cases and, with hypothermia, hypotension and lowered basal metabolic rate, reflect a state of undernutrition.

The most significant and most useful clinical test of protein deficiency is the laboratory test, the measurement of the concentration of the plasma or serum protein. Because of an apparent balance between reserve stores of protein and the essential protein of the various tissues and organs, a disappearance of the reserve protein and an encroachment on the structural and functional protein of tissues and organs appears to be reflected in a decrease in the protein, clinically detectable, of the plasma or serum.

The concentration of protein in the serum (or plasma) can be determined by several methods, but the most generally used at present is the microkjeldahl procedure, with a separation of the two fractions, albumin and globulin either by Howe's method, the modification of Robinson, Price and Hodgen [2] or the sodium sulfite method of Campbell and Hanna.[3] If only the total protein is to be determined, the new copper sulfate method of Phillips, Van Slyke and their collaborators offers an extremely simple, rapid and reliable procedure. Unfortunately albumin, the most significant fraction of the serum protein in respect to protein deficiency, may in mild and early cases be lowered significantly while the total protein remains within the normal range. In a recent study of some 1,100 subjects, 89 per cent of those with a hypoalbuminemia had normal total serum protein.[5] Furthermore, in the study of patients it is desirable to know the concentration of both albumin and globulin in relation to each other, particularly because hypoproteinemia may occur from causes other than protein deficiency and be characterized by alterations in the amounts and relative proportion of the protein fractions. Therefore, although the copper sulfate test is a very useful method for the detection of grosser changes and is particularly useful as a screening test in mass examinations, it is less well suited for the more careful study of individual patients.

Additional procedures are other adaptations of the specific gravity method [6] and the biuret (colorimetric) test.[7] The biuret colorimetric test, though simple and rapid, seems to lack reliability in the presence of other disease.

Satisfactory normal standards for the concentration of serum or plasma protein [8] of adults are those of Peters and Eisenman [9] and for children those of Dodd and Minot.[10] According to these, the normal range of total protein is from 6.0 to 8.0 Gm. per hundred cubic centimeters, for albumin 4.0 to 5.5 Gm. per hundred cubic centimeters and for globulin 1.4 to 3.0 Gm. per hundred cubic centimeters. Children above 2 years of age have the same concentration as adults.

Emphasis should be given to the significance of values but slightly below the arbitrary lower level of normal.

Physicians generally are too much influenced by the low levels of serum protein (albumin especially) encountered in hospital patients with severe disease. Relatively low concentrations do occur, without edema because the conditions (bed rest, dehydration, diuretics, restricted salt and fluid intake) are those which allow considerable hypoproteinemia without edema. But in less ill patients, in ambulatory patients and particularly in relation to nutritional protein deficiency a concentration of serum protein, especially albumin, though but slightly below the lower normal range, is apt to be significant. Furthermore, the effect of secondary factors on the relation of serum protein concentration to edema must not be forgotten; posture, salt and fluid intake and environmental temperature may operate to hinder the production of edema in the presence of even severe hypoproteinemia and under other circumstances may operate to produce it when there is only slight hypoproteinemia. These facts are mentioned because of the tendency of many to interpret protein levels on the basis of the presence or absence of edema alone.

In addition to the concentration of serum protein and protein fractions considerable significance, often too much, is attached to the albumin-globulin ratio. While alterations in this ratio are significant, the actual concentrations of albumin and of globulin are much more significant. A reversal of the ratio with serum albumin of 4.5 and serum globulin of 6.0 Gm. per hundred cubic centimeters, as in lymphopathia venereum, has a much different meaning than a reversal with the albumin 1.5 and the globulin 3.0 Gm. Too great emphasis on the reversal of the albumin-globulin ratio with neglect of the actual concentration of each fraction is incorrect.

Hypoproteinemia is by no means caused only by protein deficiency, and the mere finding of hypoproteinemia is not of itself sufficient for such a diagnosis. Fortunately, most other kinds of hypoproteinemia are characterized by abnormalities either in the blood proteins themselves or elsewhere which will help to distinguish them. The hypoproteinemia of protein deficiency is usually a proportionate decrease in both albumin and globulin, though in mild cases the globulin may remain at the usual level or rise to a high normal or even slightly above normal. Also the concentration of globulin is influenced by various infections, and it tends to respond more quickly to an increased protein intake. In cases of uncomplicated nutritional protein deficiency, severe edema does not occur except with a rather severe hypoproteinemia. In nephrosis (and nephritis), which may superficially closely resemble nutritional protein deficiency, the urinary findings are sufficient for differentiation. The edema and hypoproteinemia of an uncomplicated nutritional protein deficiency are without urinary changes or evidence of circulatory failure or venous or lymphatic obstruction. Alterations in serum proteins associated with the anemias, hepatic disease, neoplasms and various infections are apt to be characterized by a hypoalbuminemia and a hyperglobulinemia. It must not be forgotten, however, that an actual protein deficiency may accompany these and many other diseases.

The ordinary tests for serum plasma proteins measure only the concentration in the blood. Variations in blood volume can affect the concentration so that changes in total circulating protein may occur without being recognized by such tests. This fact, of great importance in acute changes in plasma protein accompanying hemorrhage, shock and some other conditions, is often lost sight of in the slower changes of nutritional protein deficiency. There is some reason to believe, however, that with a nutritional protein deficiency there may be in the early stages a significant reduction in blood volume and a decrease in total circulating blood protein. Evans [11] recently found a reduction in plasma volume in 30 per cent of a group of general hospital patients; these patients had lower than normal values for total serum protein and for serum albumin when calculations were made per kilogram of body weight, though the concentration of serum protein was normal except in a few instances.

Such a decrease in circulating blood protein could be considered an atrophy of the plasma, an atrophy such as occurs in the muscles and certain parenchymatous organs in protein deficiency. This reduction in blood volume might be the cause of some of the symptoms observed in these patients. Later the changes in blood volume are modified by the edema. As yet, however, the occurrence and clinical significance of such a possible decrease in blood volume is undetermined. If it occurs, it is apparent that a determination of blood volume as well as the concentration of serum protein will be necessary for the early diagnosis of protein deficiency.

Decrease in the serum protein concentration and particularly the relation of such a decrease to the edema may be determined by a measurement of the osmotic (oncotic) pressure of the serum or plasma. However, methods which are not well suited to clinical use such as this test are not commonly used. It is often useful, however, to calculate the osmotic pressure of the plasma (or serum), particularly in relation to the occurrence (or nonoccurrence) of edema and especially because of the greater effect of albumin than globulin on osmotic pressure. This can be done with formulas and nomograms such as those of Wells, Youmans and Miller.[12]

As yet no suitable and reliable laboratory methods exist for the detection of specific amino acid deficiency.

The physician thus has recourse to a number of procedures for determining the nutritional status with respect to protein sufficiency. The dietary history is all important. The significance of the protein content, quality and utilization, as well as other factors of the diet, should be considered. Dependent edema of a constant or transitory nature is usually the first clinical sign, and other findings of pallor, anemia and weakness sometimes appear later as associated abnormalities. Determination of the plasma or serum protein concentration is the most generally useful clinical test for the demonstration of protein deficiency. The results of this test should be scrutinized carefully when protein deficiency is suspected, however, because of the significance in ambulatory subjects of values only slightly below the lower level of normal. A knowledge of the actual values of serum albumin and globulin is of more importance than the albumin-globulin ratio. When possible the blood volume should be measured, since this may be reduced and obscure the changes occurring in the total content of body protein. The use of all diagnostic means at hand is often necessary to demonstrate the existence of early deficiency or suboptimal states of protein nutrition.

GAMMA GLOBULINS

The war caused an increased demand for blood and blood substitutes to combat battle wounds and shock. At first whole blood, because of its instability and type characteristics, did not seem to meet the requirements necessary for most efficient military application. Dried plasma was evolved; a purified concentrated solution of the albumin fraction of plasma was developed by Cohn [1] and his co-workers. Blood plasma was fractionated into several purified components by physicochemical means. Plasma proteins consist of two albumins and three globulins—alpha, beta and gamma—in addition to fractions contributing to blood coagulation and blood typing. The albumins are the proteins which are responsible for the maintenance of plasma volume and thus are important in the treatment of shock, hypoproteinemia and edema. Of the globulins, the gamma fraction is concerned with the phenomenon of immunity, for in this fraction of normal and convalescent plasma are found the substances which give high antibody titer.

The albumins are formed in the liver, but until recently the origin of the globulins remained uncertain. Dougherty, Chase and White [2] have discovered that antibodies are found in the lymphocytes and believe that the lymphoid tissue is the site of antibody formation. Many attempts have been made to separate the antibody portion of the plasma from the gamma globulins, but all have proved unsuccessful. Kass [3] has shown that the antibodies are specific modifications of the gamma globulins and that these occur in the lymphocytes, with the antigen serving as the stimulus for the modification of the gamma globulin. Thus it appears that the gamma globulins are formed in the lymphoid tissue.

The administration of either the adrenotropic hormone or the adrenal cortex steroids causes an increase in the amount of total protein of the blood. In the case of the rabbit it was found that this increase is due almost entirely to globulins. By electrophoretic means the protein present in lysed rabbit lymphocytes has been found identical to the gamma globulins of the plasma. White and Dougherty [4] believe that the pituitary-adrenal mechanism is the normal means of controlling the release of serum globulin from the reticuloendothelial cells.

As a result of the foregoing observations the origin of the plasma proteins has now been further elucidated. The albumins are known to be formed in the liver; various degrees of liver damage cause a reduction of the plasma albumin. The globulins are now believed to originate in the lymphoid tissue, and it is believed that the gamma globulins may there be modified to give rise to the various antibodies. The role of gamma globulins in medical practice promises to be increasingly important, depending on the isolation and production of purified preparations.

FLIES, FOOD AND POLIOMYELITIS

Sabin and Ward,[1] in a study of the natural history of human poliomyelitis, published in 1941, demonstrated that the human alimentary tract, from the mouth and pharynx to the colon, may be a port of entry for the virus to the body and particularly to the central nervous system. Their work was soon confirmed. The virus has also been found in human stools,[2] in sewage [3] and in flies.[4] These results, repeatedly verified by various laboratory investigators, have led to renewed studies of the transmission of the virus by flies from human stools or sewage to an uninfected person. Ward, Melnick and Horstmann [5] have now supplied direct evidence that fecal material, sewage or contact with flies by the individual, his food or fomites may actually constitute a link in the chain of infection with poliomyelitis.

Evidence with regard to the transmission by food must include proof that food merely exposed to flies in an epidemic area is infective when ingested. Such proof was obtained when food was exposed in several epidemic areas in the summer of 1944 in contact with flies in and about homes where poliomyelitis had developed within a week. The food and fly bait, exposed for

twelve and twenty-four hours, was fed to chimpanzees, care being taken to prevent cross contamination. Of the 2 animals used, neither, at any time, showed evidence of paralytic poliomyelitis but both showed virus in their stools. This virus caused typical poliomyelitis lesions in the cord and medulla of test monkeys. The virus was passed from 2 monkeys to 2 additional monkeys. The chimpanzees eliminated virus for one or two months. Neither had shown virus in the stools prior to eating the test food.

These experiments indicate that food exposed to flies at the homes of poliomyelitis patients in an epidemic area may acquire a quantity of poliomyelitis virus sufficient to produce in chimpanzees, by oral administration, a nonparalytic infection or asymptomatic carrier state. Ward and his associates believe that their conclusions may serve as additional evidence to support a working hypothesis which may be tentatively adopted to guide further investigations along similar lines. The next step might well be a control experimental study on the effect of reducing the number of flies during epidemics of poliomyelitis. As the evidence already accumulated this year indicates that poliomyelitis may be as widespread as in 1944, such a study might be carried out this summer. The efficiency of DDT in controlling flies may demand its use on a large scale when an epidemic of infantile paralysis threatens.

A NEW VECTOR FOR EQUINE ENCEPHALOMYELITIS

In a survey for the presence of type specific antibodies in the human and animal populations of the St. Louis area, Margaret Smith and her associates [1] of Washington University School of Medicine learned that few persons who had come into St. Louis County since the 1937 epidemic of encephalitis showed neutralizing antibodies specific for this virus. A large percentage of the local domestic fowls approximately 1 year of age, however, were carriers of this specific antibody. This led to the belief that some insect vector that does not bite man was mainly responsible for the spread of St. Louis encephalitis virus among domestic fowls.

Blattner [2] had shown that certain ticks (Dermacentor variabilis) become infected with this virus and transmit it by bite to susceptible animals. Infected ticks transmit the virus to their offspring for innumerable generations. Smith therefore turned her attention to the common chick mite, which belongs to the same order of Arachnida as the tick. Mites were collected from coops in which there were 2 or more chickens whose serums contained specific neutralizing antibodies for the St. Louis virus. The mites were stored in test tubes for seven to thirty days without feeding. At the end of this time 60 mites were triturated in an agate mortar in tryptose broth, and 0.1 cc. of the supernatant fluid was inoculated intraperitoneally into 11 to 19 day old Swiss mice.

Several members of each inoculated group developed typical symptoms of encephalitis. The bacteriologically sterile brains of these mice were used for the inoculation of other mice. Neutralization tests with specific antiserums showed that the virus thus propagated is qualitatively identical with the standard laboratory strain of St. Louis encephalitis virus originally isolated from a human case. Assuming that hereditary transmission of the virus takes place in infected mites, Smith concluded that infected mites may well account for the permanence of the viral infection of domestic fowls in the St. Louis area. Sporadic human cases were presumably due to an occasional mosquito borne infection from these infected domestic fowls.

Adopting a similar technic, Sulkin [3] of the Department of Bacteriology, Southwestern Medical College, collected chicken mites (Dermanyssus gallinae), fowl ticks (Argus persicus) and serums from barnyard fowls in nine ranches and farms in Dallas County, the center of the 1944 epidemic of equine encephalomyelitis. The mites and ticks were kept in test tubes for several days without feeding and then used for inoculation of both mice and guinea pigs. In a typical test a pool of approximately 100 mites was triturated in broth in an agate mortar and centrifuged at 5,000 revolutions per minute for ten minutes. The supernatant fluid was inoculated intraperitoneally into 10 to 12 day old Swiss mice or 250 gram guinea pigs.

All guinea pigs and half of the mice thus inoculated showed typical symptoms of encephalitis by the fourth to the fifth day. The bacteriologically sterile brains of these animals were used for subsequent intracerebral inoculations of other animals. Filtration experiments and neutralization tests showed that the infectious agent thus transmitted was a typical Western type strain of equine encephalomyelitis virus. Experiments are now in progress to determine whether or not hereditary transmission of this strain takes places in infected chicken mites.

Sulkin's demonstration that chicken mites presumably form a permanent depot for equine encephalomyelitis virus in Dallas County from which hens may be directly infected and man and horses infected indirectly by other insect vectors (mosquitoes) is highly significant. Practical measures to protect horses from this infection might greatly reduce the incidence of several virus diseases in man.

Current Comment

SENATOR WAGNER COMMENTS ON HIS BILL

Under Correspondence in this issue of THE JOURNAL appears a letter sent by Senator Robert F. Wagner of New York to the Editor of THE JOURNAL with the request that it be printed. In the letter Senator Wagner states unequivocally that he is opposed to state medicine or socialized medicine. He does not, however, state his definitions of state medicine and of socialized medicine. Regardless of these definitions, physicians will need to be convinced that a compulsory sickness insurance system centralized in Washington, with payments of all funds for medical and hospital care by a central agency, is neither state medicine nor socialized medicine.

IMMUNITY TO SHIGELLA PARADYSENTERIAE

The prophylactic immunization of man against bacillary dysentery has proved to be a difficult problem. At the Rockefeller Institute for Medical Research 19 healthy volunteers were divided into three groups, each of which received stated doses of a specific antigen or polysaccharide isolated from an acetone killed culture of a strain of Shigella paradysenteriae (Flexner) type V obtained from the collection of the Army Medical Center. According to Perlman,[1] all the volunteers developed a local reaction following the administration of the antigen. The reaction consisted of erythema, swelling and tenderness, which appeared in about four hours, reached a maximum in eighteen hours and completely subsided in thirty-six hours. The maximum response as measured in terms of agglutinins occurred two to three weeks after the last injection. The serum of each volunteer was tested also for agglutinins against the heterologous types of Flexner organisms. The results indicated that the antiserum evoked by the type V specific antigen agglutinates not only the homologous organisms but those of heterologous strains as well. The results indicate that the pooled serum of the immunized subjects possesses a tenfold increase in mouse protective antibodies for the homologous strain. The capacity of pooled serums to protect mice against infection with the heterologous organisms was likewise determined. This indicated a twofold increase in heterologous type Z mouse protective antibodies in the serums of the inoculated individuals. The agglutinin titer of the immunized persons fell moderately after a period of six months, but a good response was obtained with a small recall dose of antigen. Two of a group of 10 subjects inoculated with the specific polysaccharide obtained from type V organisms developed increased bacterial agglutinins. The possibility of developing a more active preparation of nontoxic nature for use in immunizing human beings to bacterial dysentery seems to be approaching.

TOLERANCE TO HEAT AND HUMIDITY AFTER ACCLIMATIZATION

Recent experience and recent experimental studies have thrown considerable light on the ability of the human body to work in hot dry or hot humid climates. Eichna and his colleagues [1] report an interesting study based on 13 volunteer white men who were subjected to varied environmental temperatures and humidity after acclimatization to dry and humid heat. The 13 men worked simultaneously, marching in single file around a 77 foot track at 3 miles per hour. Each man carried a 20 pound pack. This work rate was previously determined to amount to a total energy expenditure of 250 to 300 calories per hour. The standard work consisted of four hours of continuous marching without rest and without leaving the hot environment. At hourly intervals the men halted and stood for two to three minutes while their heart rates, rectal temperatures and respiratory rates were determined. In the more severe environments the men first worked for two hours in the morning and two hours in the afternoon before attempting the standard four hours of continuous effort. Records were kept of the symptoms, complaints and general appearance of the men during work. While in the hot environment all water drunk, urine voided and gastric contents vomited were carefully measured and recorded. The skin temperatures of six areas of the body were determined with a radiometer immediately on completion of the work. Whenever disability forced a man to discontinue marching before the standard time, the final observations were made immediately and the time was recorded. The conclusions drawn from these studies apply only to upper environmental limits determined under the conditions of the study and for environments in which the dry bulb temperature ranges between 93 and 121 F. and the wet bulb temperature between 90 and 96 F. At the upper environmental limits a narrow range of wet bulb temperature, 4 to 5 degrees F., separates environments in which work is relatively easy from those in which work is impossible. When the wet bulb temperature is below 91 F. men work easily and efficiently and suffer only mild physiologic changes. Between 91 and 94 F. wet bulb temperatures, prolonged moderately hard work is possible but efficiency is lost and the men work with difficulty, lose vigor and alertness and suffer undesirable physiologic effects. Total disability occurs in most men from moderately hard work at wet bulb temperatures of 94 F. and higher. Men who work longer than one hour at these temperatures show greatly decreased tolerance. At a dry bulb temperature of 120 F. sweating is extremely profuse, in most men averaging 2 to 3 liters per hour. This is considered the upper environmental limit for the dry bulb temperature. Above the upper environmental limits stated, acclimatized men develop severe physiologic changes and undesirable, frequently disabling symptoms similar to those sustained by unacclimatized men when first working in the heat.

MEDICINE AND THE WAR

ARMY

SURGEON GENERAL OUTLINES PERSONNEL RELEASE POLICY

Substantial releases of Army Medical Department personnel will not take place before the latter part of this year, Surg. Gen. Norman T. Kirk said in announcing a policy on discharges in conformity with War Department procedures. This is due to the fact that the peak of the Medical Department's activities will not be reached until fall.

In formulating the policy, consideration was given to civilian needs for professional medical, dental and veterinary care without weakening military needs. Other factors considered were the length of time necessary for personnel to complete their work in the Mediterranean and European theaters and return to the United States; replacement of Medical Department personnel in active theaters by those who have not had overseas duty; necessity for the maintenance of a high standard of medical care; the heavy load of patients in the United States; evacuation of the sick and wounded from Europe in the next ninety days, and continuing medical service in the Pacific.

The policy applies with equal effect to Army medical officers assigned to the Veterans Administration and other agencies.

It reads:

Medical Corps

(*a*) Officers whose services are essential to military necessity will not be separated from the service.

(*b*) Officers above 50 years of age whose specialist qualifications are not needed within the Army will receive a high preferential priority for release from active duty.

(*c*) Adjusted service ratings will be utilized as a definite guide to determining those who are to be separated.

Medical Administrative Corps

(*a*) Officers whose services are essential to military necessity will not be separated.

(*b*) Officers who express a desire to stay on duty shall be allowed to do so if vacancies exist. In the event there are more wishing to stay than there are vacancies, those with the highest efficiency index will be retained.

(*c*) Those who wish to be released will be selected on the basis of adjusted service scores.

Dental Corps

(*a*) Officers whose services are essential to military necessity will not be separated from the service.

(*b*) Officers above 50 years of age whose specialist qualifications are not needed within the Army will receive high preferential priority for release from active duty.

(*c*) Adjusted service ratings will be utilized as a definite guide in determining those who are to be separated.

Army Nurse Corps

(*a*) All nurses whose husbands have been released from active duty will be discharged on request when release of husband is proved.

(*b*) No officer will be separated whose services are essential.

(*c*) Officers with children under 18 years of age who wish to be released will receive a high preferential priority for selection.

(*d*) Adjusted service scores will govern other cases.

Medical Department Dietitians and Physical Therapists

(*a*) All Medical Department dietitians and Medical Department physical therapists whose husbands have been released from active duty will be discharged on request when release of husband is proved.

(*b*) Military necessity will govern all others. Since there is a shortage of these officers, it is not contemplated that others will be released from the service except in *a*.

Veterinary Corps

(*a*) Since there are insufficient officers to meet the present requirements, it is not contemplated that any officers will be released from the service.

Sanitary Corps

(*a*) Officers whose services are needed will not be separated.

(*b*) Officers who express a desire to stay on duty shall be allowed to do so if vacancies exist. In the event there are more wishing to stay than there are vacancies, those with the highest efficiency index will be retained.

(*c*) Those who wish to be released will be selected on the basis of adjusted service scores.

PENICILLIN SHORTENS CONVALESCENT PERIOD

According to a recent release from the U. S. Army General Hospital at Camp Pickett, Va., penicillin shortens by three to six months the average convalescence of American soldiers with limbs shattered by shrapnel or bullets in World War II. Lieut. Col. J. S. Norman, chief of the orthopedic service at Camp Pickett, stated that several million units of penicillin is administered during every twenty-four hour cycle to from 300 to 500 soldier patients. In many cases the penicillin treatment had begun immediately after a soldier was carried from the battlefield. From then on, at base hospitals overseas and on through treatment of the soldiers at army general hospitals in the United States, expert administering of penicillin continues. Almost without exception, infection is vanquished. Thus, surgery to mend shattered bones is rendered much easier and final healing itself is expedited.

Colonel Norman also stressed the improvement of other technics concerning treatment of smashed bones. In addition to the steady advance of hospital science as a whole picture, he pointed out that rapid development of traction devices and scientifically designed orthopedic braces play indispensable roles in the knitting back to normal of our fighting men's shattered limbs.

ARMY ENROLLS FULL QUOTA OF OCCUPATIONAL THERAPISTS

Mrs. W. C. Kahmann, chief of the Occupational Therapy Branch of the Army Medical Department, recently announced that occupational therapists' emergency training courses will be terminated as soon as those courses scheduled for June and July have been completed. The courses were initiated last July to overcome a serious shortage of occupational therapists in army hospitals. The full quota of students has now been enrolled, and no further application will be considered. Under this emergency training program 700 college women were enrolled and on completion of their schooling will assist in the reconditioning of army sick and wounded soldiers.

CAPTURE LARGEST NAZI MEDICAL SUPPLY DEPOT

In a recent release from the Office of the Surgeon General, it was stated that Germany's largest military medical supply depot at Ihringhausen fell into American hands recently when the 80th Infantry Division captured Kassel. According to the division surgeon, Lieut. Col. Harold J. Hallock, Winamac, Ind., it contained $100,000 worth of new surgical instruments of excellent quality, vast stores of pharmaceutical supplies and complete facilities for the production of pills, medical capsules, vials and precision instruments. Nearly 4,200 gallons of wood alcohol was found buried there.

The first army medical officer to enter the depot, Capt. Henry J. Meyer, Minneapolis, said that in strict observance of the Geneva Convention the German medical personnel left the plant and all medical supplies undamaged. All bacteriologic cultures and disease inoculated animals in the adjoining experimental laboratories had been destroyed prior to capture.

The plant and supplies will be used by the Army Medical Department to ease the drain on our own supplies by captured German military and civilian hospitals.

BRITISH GRATEFUL FOR "DEVOTED CARE"

Surg. Gen. Norman T. Kirk has received a copy of a formal letter of appreciation written by Lieut. Gen. G. N. MacReady of the British Joint Staff Mission on the liberation of British prisoners of war in the Philippines. Gen. Sir Ronald S. Adam, Adjutant General to the forces, is quoted in the letter as stating that all British prisoners liberated from Cabanatuan and Bilibid "speak in glowing terms of the devoted care given to them by American troops after their release, as well as of the excellent administrative and medical arrangements made in the Southwest Pacific area and in the United States for their homecoming." The letter conveys "the deep appreciation and warm thanks" of the British Army Council to all concerned.

ARMY AWARDS AND COMMENDATIONS

Captain Logan B. Hull

Capt. Logan B. Hull, formerly of Altoona, Pa., was recently awarded a special commendation for the magnificent way he and medical units under his command performed their duties handling heavy American casualties in September and October near Andelst, Holland. The citation read "It is recommended that Capt. Logan B. Hull, M. C., Capt. Samuel C. Feiler, D. C., 1st Lieut. Everett C. Vogt, M. A. C., the enlisted men of the regimental headquarters section, medical detachment, this regiment (the 506th parachute infantry) and the men attached to this section from the 326th medical company, be cited in orders or receive a letter of commendation for the prompt and efficient treatment and evacuation of over 700 United States and Allied casualties from Sept. 17, 1944 to Oct. 11, 1944. Over 200 of these casualties were treated between Oct. 5 and 7, 1945 in the vicinity of Andelst, Holland, during which period all personnel worked for over thirty-six hours without sleep and under intermittent fire, one 210 mm. shell passing through the roof of the aid station and exploding in the front courtyard. This service, though within the call of duty, was carried out so efficiently and faithfully throughout this period of time that the early recovery of many was assured and the lives of some of our soldiers were saved by the meritorious actions of Captain Hull and those under his command." Dr. Hull graduated from the University of Pittsburgh School of Medicine in 1939 and entered the service Feb. 1, 1941.

Lieutenant Colonel J. Roy Theriot Jr.

The Bronze Star was recently awarded to Lieut Col. J. Roy Theriot Jr., formerly of Houston, Texas, for his untiring efforts in reducing the sickness rate and number of lost man hours, and improving the general health of the 8th Air Force Service Command. He received the Presidential Unit Citation when with the 95th Bomb Group before his assignment to the 8th Air Force Service Command. Dr. Theriot graduated from Tulane University of Louisiana School of Medicine, New Orleans, in 1930 and entered the service May 14, 1942.

Captain Merwin E. Buchwald

The Bronze Star was recently awarded to Capt. Merwin E. Buchwald, formerly of Brooklyn, for heroic achievement in action on the Fifth Army front in northern Italy. He is serving with the 178th Field Artillery Battalion, attached to the second corps. Dr. Buchwald graduated from Duke University School of Medicine, Durham, in 1941 and entered the service March 27, 1943.

Captain Milton M. Sisson

Capt. Milton M. Sisson, formerly of Greenfield, Mass., was recently awarded the Bronze Star for meritorious service in combat from May 6, 1944 to October 1944 in Italy. The citation accompanying the award read "On Sept. 27, 1944, Company C collecting station was located one mile south of Caestel del Rio, Italy, when the rain washed out a by-pass, blocking the route of evacuation to the rear. As a result, 44 casualties accumulated at the station. By his foresight Captain Sisson had a sufficient stock of food, dry clothes and medical supplies to care for the great influx of patients during the emergency. During the night the area was subjected to an intense enemy artillery barrage, scoring two direct hits on the station. Throughout the barrage Captain Sisson coolly made his rounds, reassuring the patients and comforting them to prevent panic. Captain Sisson showed his continuous initiative by devising a rubber stamp form for the supplemental medical record of the emergency medical tag. This stamp was accepted as a standard for all companies of the medical battalion. His inspirational leadership, calm manner, mature medical judgment and constant devotion to duty has resulted in establishing the highest ideals for medical service." Dr. Sisson graduated from Tufts College Medical School, Boston, in 1932 and entered the service in October 1943.

Major Evan L. Garrett

The Bronze Medal and citation was recently awarded to Major Evan L. Garrett, formerly of Murray, Ky., "for meritorious service in connection with military operations against an enemy of the United States from Aug. 19, 1944 to Feb. 19, 1945. Major Garrett, chief of the surgical service, Sixth Convalescent Hospital, distinguished himself by his outstanding performance of duty. The exceptional professional skill he displayed was an important contribution to the high standards of efficiency achieved and maintained by his organization; his accomplishments and loyal, untiring devotion to duty reflect great credit on himself and on the military service." Dr. Garrett graduated from the College of Medical Evangelists, Los Angeles, in 1936 and entered the service April 22, 1941.

Captain Adrian Z. Leon

Capt. Adrian Z. Leon, formerly of New York, was recently awarded the Bronze Star "for meritorious service in action. During the period Nov. 30 to Dec. 1, 1944 in the vicinity of Dambache-la-Ville, France, Lieutenant Leon tirelessly and diligently treated the wounded under the most trying conditions. Working night and day, he taxed his professional skill to its utmost, enabling many of the lighter casualties to return to the line. Taking no heed of personal physical exhaustion, he was always available when conditions necessitated his presence. His superb ability and untiring efforts served as an inspiration to all." Dr. Leon graduated from the University of Montpellier Faculty of Medicine, France, in 1936 and entered the service early in 1944.

Major Anthony A. Nardone

Major Anthony A. Nardone, formerly of Philadelphia, was recently awarded the Bronze Star for meritorious service in Germany from Nov. 16, 1944 to Feb. 1, 1945 in connection with military operations against the enemy. As regimental surgeon Major Nardone performed his duties in an outstanding manner. Because of his tireless efforts he achieved a highly efficient system in his detachment which contributed greatly to saving the lives of wounded men. His devotion to duty and consistent effort reflect great credit on himself and on the military service. Dr. Nardone graduated from the University of Pennsylvania School of Medicine, Philadelphia, in 1929 and entered the service March 1, 1941.

Lieutenant Colonel Joseph H. Clevenger

The Bronze Star was recently presented to Lieut. Col. Joseph H. Clevenger, formerly of Muncie, Ind., for meritorious service. Dr. Clevenger, who has been commanding officer in charge of a field hospital, left his unit in Belgium recently because of injuries and has been returned to this country for treatment. The field hospital of which he was in command also has been awarded the meritorious service unit plaque. Dr. Clevenger graduated from Northwestern University Medical School, Chicago, in 1927 and entered the service Aug. 13, 1942.

Captain Shepard G. Aronson

The Bronze Star was recently bestowed on Capt. Shepard G. Aronson, formerly of Brooklyn, "for meritorious achievement in connection with military operations against the enemy at . . . from . . . to . . . Captain Aronson personally directed the officers and enlisted personnel of a surgical operating room in addition to performing surgery himself, giving life saving service to liberated civilian internees, military personnel and Filipino guerillas at a site which was receiving enemy artillery fire. He continued his heroic leadership through a time when three shells struck the front of the building and numerous others fell in the adjacent frontal area. One burst was so close that flying glass, plaster and shell fragments caused casualties in the operating room. Twice, when shells were falling most frequently, it was suggested by the commanding officer of the hospital that he temporarily seek safety, but Captain Aronson elected to continue. He had about ten hours' rest during the five day period. Through his tireless, skilful and creditable behavior not only lives and limbs were saved but hundreds of people were influenced with a spirit of order at a time and place threatened by chaos." Dr. Aronson graduated from Cornell University Medical College, New York, in 1937 and entered the service Oct. 12, 1942.

Captain Herman F. Van Ark

The Silver Star was recently awarded to Capt. Herman F. Van Ark, formerly of Hartford, Wis., for gallantry in action. The citation was for rescuing two wounded American soldiers under heavy fire in France. Dr. Van Ark graduated from Marquette University School of Medicine, Milwaukee, in 1942 and entered the service Feb. 22, 1943.

Colonel Neville M. McNerney

The Bronze Star was recently awarded to Col. Neville M. McNerney, formerly of Cleveland Heights, Ohio. He has been serving as a commanding officer of a hospital center in England and he also acts as an inspector for a group of army hospitals. Dr. McNerney graduated from the Cleveland-Pulte Medical College in 1913 and entered the service Oct. 15, 1940.

MISCELLANEOUS

RED CROSS HOSPITAL PROGRAM NEEDS 3,000 WORKERS

The American Red Cross needs 750 trained social workers at once for supervisory, administrative and staff positions in military hospitals, largely in the United States. The wounded and disabled returned to this country for further treatment need the skilled help of trained and experienced social workers. New and higher salary schedules, ranging from $170 to $350 monthly, depending on education, experience and job assignment, have been adopted by the Red Cross, as have also annual increments and promotions. Quarters are provided and, if not available at the hospital, an additional allowance is made. Free uniforms are also issued.

In addition 1,650 untrained and partially trained workers are needed by the Red Cross to serve in the area of social case work under professional guidance. Salaries range from $140 to $200 monthly. The hospital program also calls for 600 recreation workers at monthly salaries of $150 to $325.

The project for which these 3,000 hospital workers are being recruited will continue for many years. Despite this, however, employment will be offered by the Red Cross to any qualified workers willing to serve a minimum of one year. Applications should be filed at the nearest Red Cross area office: North Atlantic Area, 300 Fourth Avenue, New York 10; Eastern Area, 615 N. St. Asaph Street, Alexandria, Va.; Southeastern Area, 230 Spring Street N.W., Atlanta 3, Ga.; Midwest Area, 1709 Washington Avenue, St. Louis 3, and Pacific Area, Civic Auditorium, Larkin and Grove streets, San Francisco 1.

WARTIME GRADUATE MEDICAL MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

California

Station Hospital, Chico Army Air Field: The Pneumonias, Dr. Henry D. Brainerd, June 24.

Station Hospital, Stockton Army Air Base: Experiences with Infectious Diseases in Army Camps in England, Dr. Gordon E. Hein, June 27.

Birmingham General Hospital, Van Nuys: Observations on the Management of Burns and Their Plastic Repair, Capt. Harold L. D. Kirkham, June 27.

A. A. F. Regional Hospital, March Field, Riverside: Peritoneoscopy, Capt. John Ruddock, June 19.

U. S. Naval Hospital, Long Beach: Pathogenesis of Rheumatic Fever, Lieut. Comdr. Robert W. Huntington Jr., June 20.

U. S. Naval Hospital, Corona: Surgical Conditions of the Liver and Its Ducts, Capt. E. E. Larson, June 28.

Station Hospital, Camp Cook, Lompoc: Cardiac Pain, Capt. Arthur Twiss, June 20.

Hoff General Hospital, Santa Barbara: Cardiac Pain, Capt. Arthur Twiss, June 20.

A. A. F. Regional and Convalescent Hospital, Santa Ana Army Air Base; Differential Diagnosis of Hysterias, Dr. John Neilson, June 19.

U. S. Naval Hospital, Santa Margarita Ranch, Oceanside: Injuries of the Ureter, Lieut. Comdr. C. P. Rusche, June 14; Selection of Proper Agent and Method in War Surgery, Lieut. L. E. Trotter, June 28.

Indiana

Billings General Hospital, Fort Benjamin Harrison: Psychosomatic Medicine, Dr. David Slight, June 13; Wound Healing and Tendon Surgery, Dr. Sumner Koch and Lieut. Col. Preston, June 20; Mental Hygiene and the Prevention of Neuroses in War, Col. William J. Bleckwenn, June 27.

Wakeman General Hospital, Camp Atterbury: Mental Hygiene and the Prevention of Neuroses in War, Col. William J. Bleckwenn, June 13; Thrombosis, Thrombophlebitis and Anticoagulants in Less Common Peripheral Vascular Diseases, Major Reed and Dr. Robert McVandivier, June 20; Peptic Ulcer, Gallbladder and Liver Diseases, Drs. Lester Dragstedt and W. D. Gatch, June 27.

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service:

(Continuation of list in THE JOURNAL, May 26, page 295)

ILLINOIS

Lutheran Deaconess Home and Hospital, Chicago. Capacity, 218; admissions, 6,265. Mr. E. E. Hanson, Superintendent (2 interns, October 1).

MICHIGAN

City of Detroit Receiving Hospital, Detroit. Capacity, 640; admissions, 17,540. Dr. R. R. Piper, Medical Superintendent (assistant resident—otolaryngology, July 1).

MISSOURI

Alexian Brothers Hospital, St. Louis. Capacity, 176; admissions, 2,163. Brother Athanasius, R.N., Superintendent (resident—mixed service, July 1).

Christian Hospital, St. Louis. Capacity, 135; admissions, 2,925. Miss Mildred Morris, R.N., Superintendent (interns).

NEW YORK

Goldwater Memorial Hospital, New York City. Capacity, 1,660; admissions, 1,676. Dr. C. G. Scherf, Medical Superintendent (6 interns, July 1).

Lincoln Hospital, New York City. Capacity, 469; admissions, 9,546. Dr. Herman E. Bauer, Medical Superintendent (resident—medicine, assistant resident—medicine, July 1).

St. Agnes Hospital, White Plains. Capacity, 177; admissions, 2,695. Sister M. Madeline, R.N., Superintendent (interns).

SOUTH CAROLINA

Greenville General Hospital, Greenville. Capacity, 355; admissions, 8,515. Mr. J. B. Norman, Superintendent (interns).

ORGANIZATION SECTION

Washington Letter

(From a Special Correspondent)

June 4, 1945.

Congress Favors Bill to Create Veterans Medical Department

Both sides of the House are favorably disposed toward the proposed Veterans Administration reorganization which would establish a bureau of medicine and surgery within the agency, having independent status similar to the Army and Navy Medical Corps. In fact, both Republicans and Democrats claim credit for the idea. Democratic Representative Rankin, who introduced a bill which Representative Rogers, Republican of Massachusetts, said she "had been working on for months," said the measure would give the Veterans Administration power to replace "undesirable" members of its present medical and nursing staffs.

Veterans Administrator Hines has submitted for approval of the Federal Board of Hospitalization what he describes as "the greatest hospital construction program ever undertaken by the administration." He said that it contemplates either construction of or additions to seventy-three facilities located in all parts of the United States and will provide 26,772 beds, of which 15,333 are for general medical and surgical, 2,413 for tuberculous and 8,137 for neuropsychiatric patients, and the other 889 for domiciliary members. The cost of the program is estimated at $180,000,000. In addition to the new beds already provided, General Hines said that the Veterans Administration is now constructing new facilities or additions to existing facilities that will provide 13,525 beds. Other construction being developed will provide 16,442 more. He explains that plans are already launched to provide a total of 133,075 hospital beds, which compares with 61,845 at the time of Pearl Harbor. Of these projected beds 90,073 will be ready for occupancy this year and 105,762 will be completed in 1946. These figures do not include the 14,079 domiciliary beds in existence at present.

Chemical Manufacturers Standardize Labeling

The Manufacturing Chemists Association announces that the "first comprehensive effort" to systematize and standardize the labeling of hazardous chemicals has been completed after a year's work and results are being published. A manual titled "A Guide for the Preparation of Warning Labels for Hazardous Chemicals" has been prepared by a special labels and precautionary information committee of the association. The principal objective is to discourage dependence on code labels which leave the user with no information about the product. The manual outlines the principles that should govern preparation of precautionary labels, with emphasis on protecting the users, handlers, repackers, jobbers and distributors of chemical products and others who may be less familiar with them than the manufacturers. Basic considerations in preparation of precautionary labels are regarded as (1) determination of hazards present in the particular chemical, (2) selection of appropriate statements for each hazard and (3) arrangements of statements in order of emphasis desired.

Labor Secretary Perkins to Testify Before Committee

Secretary of Labor Frances M. Perkins will testify June 6 before the House subcommittee investigating aid to the physically handicapped in what will be one of her last official appearances on Capitol Hill before she resigns July 1 to be succeeded by Judge Schwellenbach. Secretary Perkins will describe the accident program sponsored by the Bureau of Labor Standards. Chairman Augustine B. Kelley, Democrat of Pennsylvania, has asked her for recommendations which might be followed by the government to reduce accidents in industry.

Scheduled also to testify are William H. Ivey and Lewis E. McBrayne of the National Committee for the Conservation of Manpower in Industry. To be heard June 7 are John W. Gibson, president of the Michigan C. I. O. Council and former Michigan state commissioner of labor, J. A. Haller of the Maryland State Industrial Accident Commission and Fred C. Thomas, director of the District of Columbia Industrial Safety Division.

Criticism of Navy Promotions by Civilian Dentists

Navy dental officers have "no chance for advancement," charged Dr. Sterling V. Mead, president of the American Dental Association, in testimony before the Senate Naval Affairs Committee, on a bill to separate the Navy medical and dental departments. Vice Admiral Ross T. McIntire, head of the departments and formerly personal physician to President Roosevelt, has opposed the bill, declaring that to separate the two departments would lessen morale and affect medical attention to personnel aboard a ship. The dental officials pointed out that the highest rank a dental officer in the fleet or the Marine Corps field service can get is lieutenant commander. Dental officials accuse the Navy of resorting to "reprisals and insincerity" in treatment of dental officers and personnel.

Extension of Policy on Providing Prosthetic Appliances

Veterans Administrator Hines has announced in a letter to all agency stations that the policy has been extended on provision of supplementary or emergency limbs to include braces and other types of prosthetic appliances. How many veterans will be affected cannot now be estimated. The Army alone has reported 8,470 leg amputations and 2,530 arm amputations. The Navy has not issued comparative figures. The number of veterans who will require other types of prostheses or artificial limbs is said to be entirely "problematic."

Appeal Opposed in Vitamin D Patent Suits

Claiming a misleading presentation of facts, Vitamin Technologists, Inc., of Los Angeles, has opposed the appeal of the Wisconsin Alumni Research Foundation for a Supreme Court hearing of the suit. The vitamin corporation, in a brief urging the court to refuse to hear the case, complained that the foundation had raised questions pertaining to a misuse of the patents which could not be presented "because the Ninth Circuit Court of Appeals does not base its decision on that ground." Patents cover the use of vitamin D in the treatment of rickets and are based on discoveries of Dr. Harry Steenbock, Wisconsin University professor, in producing vitamin D in foods and medicines by exposure to ultraviolet rays.

Election of Dr. William P. Herbst Jr.

Dr. William P. Herbst Jr. has been chosen president-elect of the Medical Society of the District of Columbia, with Dr. Fred A. J. Geier first vice president, Dr. Dorothy S. Jaeger second vice president, Dr. William M. Ballinger member of executive board, Dr. Coursen B. Conklin delegate to the American Medical Association, Dr. Arch L. Riddick alternate and Dr. Harry F. Dowling member of the board of censors. Dr. William Earl Clark, who was named president-elect last year, will take over as president of the society on July 1.

Lieut. Col. James N. Greear Jr., this year's president, was ordered overseas several months ago, and on his departure Dr. William N. Ballinger was appointed acting president and will serve until Dr. Clark is installed. The board of censors has recommended to the society "the desirability of amending the society's constitution and by-laws so that applicants will be accepted for a probationary period of one year and be elected by the excutive board rather than by the society's membership. Reasons are that (1) it is difficult to determine in

advance the desirability of a physician as a member and (2) only a few members take an active part in the election of new members.

Well received was the address by Dr. Joseph S. Lawrence, executive director of the Council on Medical Service and Public Relations, head of the Council's Washington office, who discussed "Public Opinion will Determine Medicine's Future."

Secretary Theodore Wiprud, secretary of the society, reported a steady increase in membership from 1,118 in 1941 to 1,?25 in 1945.

Meeting of Regional Civil Service Commission Doctors

The responsibility of the Civil Service Commission in the medical field was explained when chiefs of regional medical divisions met here. Placement of the physically handicapped and problems relating to various regions were discussed. Speakers included Dr. Schoul Levison, Boston; Dr. Maurice Klein, Cincinnati; Dr. Frank Patterson, St. Louis; Dr. F. J. Fanning, Seattle, and Dr. Francis Quinn, San Francisco.

One Adult in Seven Dies of Cancer, Dr. Adair States

Guests at a luncheon of the District of Columbia cancer campaign included members of scientific, legislative, business and welfare groups of Washington. Dr. Frank Adair explained that the present United States cancer mortality rate is so high that one adult in seven can expect to die of the disease.

Capital Notes

The Senate passed and sent to the House a bill amending the District of Columbia code so that either before trial or after conviction a defendant in a criminal case may be sent by judges of the local courts to Gallinger Municipal Hospital for mental examination.

Employee preventive health services made possible the employment of persons with diabetes, hitherto lost to industry, in air line "ground positions" during the manpower shortage, Dr. L. G. Lederer, medical director of Pennsylvania-Central Airlines, states.

Long the medical guardians of the late President Roosevelt, Bethesda civilian and naval personnel are wondering whether President Truman, as an Army man, will go to Walter Reed hospital if he needs medical attention.

The Navy needs 4,000 additional reserve officers in its Medical Corps, and physicians who are interested should get in touch either with the Naval Officer Procurement Branch in Washington or with their local procurement and assignment service.

Need to coordinate Washington's psychiatric diagnostic services with other community public services was stressed at meetings of the Committee on National Conference of Social Work.

The District commissioners were asked to lend support to construction of a $557,000 home in the country for rehabilitation of Washington alcoholic addicts.

Dr. Janvier W. Lindsay, aged 64, was none the worse after the experience of being kidnapped by three men while hurrying to the bedside of a young patient with life saving plasma. He is pathologist and staff physician at the Episcopal Eye, Ear, Nose and Throat Hospital.

Six tons of protein hydrolysates, the largest consignment of drugs ever to leave this country, was shipped to a Dutch port to help save the lives of thousands of starving Hollanders.

Infantile paralysis is increasing in New England and in the Middle and South Atlantic states this year, but only 2 cases have been reported in Washington this year, according to Dr. James E. Cumming, chief of the Bureau of Communicable Diseases.

Bureau of Information

COMPLETE REPORTS FROM ARIZONA, LOUISIANA, NEVADA, WISCONSIN AND THE DISTRICT OF COLUMBIA

Completed county summary sheets have been received from Dr. Frank J. Milloy, Dr. P. T. Talbot, Dr. M. J. Thorpe and Mr. C. H. Crownhart, secretaries of the State Medical Societies of Arizona, Louisiana, Nevada and Wisconsin respectively and from Mr. Theodore Wiprud, secretary of the Medical Society of the District of Columbia.

1. Bureau of Census, estimated population 1943.
2. Bureau of Census, population 1940.
3. Based on 1940 figures, American Telephone and Telegraph Company.

The accompanying table gives data from counties in each of these states. The column giving the number of persons per telephone is used as one index of the economic status of the area. Many physicians over 65 years of age are carrying on large practices and are doing much to maintain the health of communities. They are not included in computing physician population ratio, however, as the future needs of the communities will be largely dependent on younger physicians.

A current knowledge of needs of communities for doctors is essential if adequate help is to be given veteran medical officers in their problems of medical practice. These needs can be indicated on the summary sheets under "Remarks" by the sta-

and county secretaries and are then available to inquiring medical officers. Frequent reports from state and county medical societies about needs of communities for doctors will help maintain current files and will increase the service of the Bureau.

With the information available on a completely filled out summary sheet, it is readily possible for an interested medical officer to make an initial selection of areas in which he might like to practice. Since vacancies are held open in many communities for doctors now in military service, further investigation by direct correspondence with state and county medical societies will always be necessary to insure an accurate report of the needs of individual communities.

Medical Legislation

MEDICAL BILLS IN CONGRESS

Social Security Act

On May 24 Senator Wagner, New York, for himself and Senator Murray, Montana, introduced his revised bill purporting to provide for the national security, health and public welfare, S. 1050. Representative Dingell, Michigan, introduced the companion bill in the House, H. R. 3293. An analysis of a part of this bill was published in THE JOURNAL, June 2. Other analyses will be published in early issues of THE JOURNAL.

A bill introduced by Representative Stewart, Oklahoma, S. 1021, contemplates an amendment to the Social Security Act to enable self-employed individuals to secure coverage under its old age and survivors' insurance provisions.

Veterans Administration

Representative Rankin, Mississippi, introduced on May 25 a bill to establish a Department or Bureau of Medicine and Surgery in the Veterans Administration, H. R. 3310. Representative Rogers, Massachusetts, introduced a similar bill, H. R. 3317, and a companion bill was introduced in the Senate by Senator Johnson, Colorado, S. 1079.

In addition to proposing a reorganization of the medical facilities of the Veterans Administration, these bills provide that any personnel needs of the several corps to be created in the Veterans Administration, including a Medical Corps, may be filled by assignment of selected or drafted persons and that commissioned, appointed or enlisted medical personnel of the Army or Navy may be detailed for service with the Veterans Administration when such detail, in the judgment of the heads of the agencies concerned, or of the President, will promote the public interests without impairing the efficiency of the service or services involved. Preliminary consideration was given to this legislation by the House Committee on World War Veterans' Legislation, May 29, and further consideration was postponed to a later date.

Representative Cannon, Florida, has introduced H. R. 3200 to provide that veterans shall not be denied care or treatment in Veterans Administration facilities for mental or nervous disorders because they have not been adjudged mentally incompetent.

Another bill introduced by Representative Barry, New York, H. R. 3332, would eliminate financial inability to defray expenses of hospital treatment or domiciliary care as a condition precedent to obtaining such treatment or care in a Veterans Administration facility.

Two bills, S. 977, introduced by Senator Morse, Oregon, for himself and Senator Cordon, Oregon, and H. R. 3337, introduced by Representative Harless, Arizona, propose aid in providing housing for veterans attending educational institutions under the G. I. Bill of Rights.

Brigadier General Hines has recommended to the Federal Board of Hospitalization, according to newspaper accounts, a $180,000,000 Veterans Administration hospital building program.

Selective Training and Service Act

Representative Judd, Minnesota, has introduced in the House of Representatives H. R. 3350, a bill to authorize the release of persons from active military service, and the deferment of persons from military service, in order to aid in making possible the education and training of physicians and dentists to meet essential needs. This bill, referred to the House Committee on Military Affairs, is substantially the same as the measure introduced by Senator Ellender, S. 637.

Industrial Health

The House Committee on Labor has reported, with amendments, the bill introduced by Representative Norton to provide for cooperation with state agencies administering labor laws in establishing and maintaining safe and proper working conditions in industry and in the preparation, promulgation enforcement of regulations to control industrial health haza One amendment would provide that in the operation of st plans the services and facilities of public health services in field of industrial hygiene shall be utilized to the extent t such services may be made available to the labor departme of the several states.

Physically Handicapped Persons

The House Committee on the Judiciary has reported H. Res. 23 with amendments, designating the first week in Octob of each year as National Employ the Physically Handicappe Week.

A bill introduced by Senator Myers, Pennsylvania, S. 98 seeks to prevent discrimination against blind persons and person with impaired visual acuity in the administration of the civ service laws and rules.

Health Education

Representative Landis, Indiana, has introduced H. R. 3055 to provide funds to assist the several states and territories in making adequate provisions, through the public schools, for physical education, educational health service, wider recreational use of school facilities and vocational guidance. This bill proposes an appropriation of $40,820,000 for each fiscal year. The sum of $92,000 will be allotted to each state for each Congressional district, $46,000 to be used in connection with programs of physical education and $46,000 to be used in connection with programs of vocational guidance. The provisions of this bill will be administered on a federal level by the United States Commissioner of Education.

Miscellaneous

The President has submitted a supplemental estimate in the amount of $2,300,000 for use in connection with the EMIC program for the fiscal year ending June 30 next.

S. 1037, introduced by Senator Barkley, Kentucky, would provide for water pollution activities by the United States Public Health Service.

A bill introduced by Senator Langer, North Dakota, S. 836, would authorize the appropriation of additional funds to assist the states and territories in promoting and financing vocatio and other training.

District of Columbia

Two bills would remove the restrictions to the appointme of retired officers of the United States Public Health Servi as superintendent of Gallinger Municipal Hospital in the Distri of Columbia, S. 1067, introduced by Senator Bilbo, Mississipp and H. R. 3257, introduced by Representative Randolph, Wes Virginia.

Two other bills, S. 1008, introduced by Senator Bilbo Mississippi, and H. R. 3236, introduced by Representativ McMillan, South Carolina, would enlarge the authority of th commissioners of the District of Columbia to make regulation to prevent and control the spread of communicable and pre ventable diseases.

Official Notes

COMMITTEE VISITS PRESIDENT TO URGE DEFERMENT OF PREMEDICAL AND MEDICAL STUDENTS

On May 31 a committee, including Dr. Evarts Graham, St. Louis, Dr. Victor Johnson, Secretary, Council on Medical Education and Hospitals, Chicago, Dr. Harvey Stone, member of the Board, Procurement and Assignment Service, Baltimore, and Dr. Fred C. Zapffe, Secretary of the Association of American Medical Colleges, Chicago, representing the Committee on Postwar Medical Service, called on the President of the United States in order to present to him a memorandum dealing with the supply of premedical and medical students, and physicians. Attention was called to the increased need of physicians by the civilian population, the Veterans Administration and the armed forces in the years to come. Within the next year the number of admissions of freshmen to medical schools will be reduced by about 5,000 because of the existing policies, and a corresponding reduction in the available physicians will follow. A complete memorandum is being forwarded directly to the President at his request in order to place all of the facts before him.

ELECTRICAL TRANSCRIPTIONS: KEEP COOL

In the good old summertime health problems exist just as at other times of the year, but they are very special health problems and many of them more nuisance than actual menace. Yet they do tend to spoil the vacation and detract from summer sports and relaxation. With this in mind the American Medical Association through the Bureau of Health Education offers to county medical societies a new series of twelve transcriptions under the title Keep Cool:

1. Suntan
2. Sunstroke and Heat Exhaustion
3. Exercise in the Summer
4. Health in Swimming
5. Water Safety
6. Light Summer Meals
7. Bugs
8. Poison Ivy
9. Keeping Cool
10. Hiking and Biking
11. Picnic Lunch
12. Hay Fever Time

These platters are twelve interviews with Dr. W. W. Bauer, interviewed by June Merrill of the staff of radio station WJJD, Chicago. These extremely informal conversations are recorded on ten minute platters, leaving four minutes and thirty seconds of the usual quarter hour of radio time for local use. Recommendations for such use are:

1. That the local medical society or health department designate a speaker to add local "angles" to the transcribed program.

2. That the radio stations be requested to fill in the time with recorded music.

3. That the transcription be "teamed" or bracketed with a five minute news summary, preferably with the news summary first followed by the transcription.

As with most transcriptions made available by the American Medical Association, these may be borrowed without charge by local medical societies or reputable local agencies when the loan is approved by the local medical society. The only expense to local groups is the nominal express charge for returning the records.

With the announcement of this series the Bureau of Health Education now offers a well rounded program of electrical transcriptions including Before the Doctor Comes (sixteen programs), Medicine Serves America (ten programs), Dodging Contagious Diseases (twelve programs), Live and Like It (twelve programs dramatized), More Life for You (thirteen programs) and the series announced herewith.

A separate series, Health Heroes, for use in elementary schools is also available but by purchase only.

Descriptive circulars will be sent on application. Address the Bureau of Health Education, American Medical Association, Chicago 10.

DOCTORS LOOK AHEAD

The current series of network broadcasts by the National Broadcasting Company and the American Medical Association will terminate with the program scheduled for June 30. Plans for a 1946 series will be announced in THE JOURNAL when ready.

Doctors Look Ahead is broadcast each Saturday at 4:30 p. m. Eastern War Time (3:30 p. m. Central War Time, 2:30 p. m. Mountain War Time and 1:30 p. m. Pacific War Time) except in Chicago, where each week's program as broadcast on the network will be heard on the next Saturday afternoon at 3 o'clock Central War Time.

The programs remaining to be broadcast are as follows:

June 9. They Shall Hear Again: A program devoted to the needs of the hard of hearing and indicating new opportunities for them through the use of hearing aids, lip reading, medical treatment and occasionally surgery. Guest speaker Howard A. Carter, B.S. in M. E., Secretary of the American Medical Association Council on Physical Medicine.

June 16. Home Was Never Like This: A program devoted to the possibilities of the American health resort or spa in the treatment of disease. Guest speaker Dr. Walter S. McClellan, chairman of the American Medical Association Committee on Health Resorts, speaking from New York.

June 23. Postwar Doctor: Problems in medical education and their influence on the public health. Guest speaker Dr. Victor Johnson, Secretary of the American Medical Association Council on Medical Education and Hospitals.

June 30. Health in Schools: A program devoted to health education and related topics in our schools, where doctors look ahead to greater progress in the next decade. Speaker Dr. Charles C. Wilson, Teachers College, Columbia University, speaking from New York.

Woman's Auxiliary

South Carolina

Col. Howard J. Hutter, post surgeon at Camp Croft Station Hospital, was guest speaker at the meeting of the Woman's Auxiliary to the Spartanburg County Medical Society recently. Colonel Hutter, an army medical officer in charge of the medical setup in the North African area, told of the work involved in choosing hospital sites, caring for the evacuation of the sick and wounded, maintaining medical supplies and establishing sanitation in North Africa. Stereopticon pictures of the hospital and supply depots in Oran and Sidi-bel-abbes were also shown.

Texas

The Neuces County auxiliary is compiling a list of names of blood donors to be made available to all physicians and hospitals in Corpus Christi as their first wartime project. The file will be kept at the Physicians Exchange.

Wyoming

The Woman's Auxiliary to the Sweetwater County Medical Society was organized last December. This is the first county to organize itself since the state auxiliary reorganized last year. Sweetwater County has done exceptional work in the Cadet Nurse project. Twenty-eight of its young women are now serving in hospitals throughout the state.

Medical Economic Abstracts

MICHIGAN MEDICAL SERVICE LIBERALIZES BENEFITS

Because of its financial experience, Michigan Medical Service has liberalized its benefits without increasing its rates. Effective April 1, the Medical Service removed the previous limit of $150 for surgical services provided under its schedule of benefits and performed at the same time or for the same condition, shortened the maternity waiting period from ten to nine months, removed entirely the waiting period on other obstetric conditions and provided for emergency surgical services for doctors in hospital outpatient departments. Nearly 800,000 subscribers were affected by the liberalization.

According to Dr. R. L. Novy, Michigan Medical Service president, group requests for enrolment in the Medical Service have risen to a new peak.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Gift to Alabama Medical College.—The Alabama Division of the Field Army of the American Cancer Society has presented to the Medical College of Alabama a set of 100 microscopic slides for study of cancer and other tumors. The slides were purchased from the Central Bureau for the Study of Tumors in Philadelphia.

Allied Health Council Organized.—The Allied Health Council of Alabama was recently organized to coordinate the activities of various health groups and to conduct an educational campaign to increase interest in the state's public health work. C. B. Bray, president of the Alabama Dental Association, and Mrs. Thelma M. Coburn, executive secretary of the Alabama Pharmaceutical Association, were named president and secretary treasurer respectively. The executive board consists of B. F. Sapienza, representing the Alabama Dental Association, Mrs. Walter Bragg Smith, representing the state nurses' association, Elbert W. Gibbs, representing the Alabama Pharmaceutical Association, Clyde L. Sibley, representing the Alabama Hospital Association, and Dr. Burton F. Austin, Montgomery, state health officer, representing the state health department.

CALIFORNIA

Howard Karsner Lectures.—Dr. Howard T. Karsner, professor of pathology and director of the Institute of Pathology, Western Reserve University School of Medicine, Cleveland, addressed the Los Angeles Academy of Medicine, May 11, on "Tumors of the Endocrine Glands."

County Society Opens New Offices.—The Alameda County Medical Association has rented the entire fifth floor of the Income Securities Building, 364 Fourteenth Street, Oakland, for its business office. The new executive secretary of the association is Mr. Rollen Waterson, who formerly held a similar position with the Lake County Medical Society, Hammond, Ind. (THE JOURNAL, March 31, p. 865). The Alameda County Medical Association has also chosen an attorney, Mr. Harold Huovinen, to advise in organizational business and tax problems.

Lectures on Psychoanalysis.—The San Francisco Psychoanalytic Society opened a course of lectures for physicians on "Introduction into Psychoanalysis" May 23. Dr. Jacob S. Kasanin, San Francisco, gave the first lecture, on "Psychoanalysis as a Medical Science." Other lecturers in the series include:

Siegfried Bernfeld, Ph.D., San Francisco, The Method of Psychoanalysis, May 30.
Dr. Erik H. Erikson, Berkeley, Etiolc [illegible] 6.
Dr. Bernhard Berliner, San Francisco, June 13.
Dr. Donald A. Macfarlane, Berkeley, erence in Medical Practice, June 20.
Dr. Emanuel Windholz, San Francisco, Psychosomatic Medicine, June 27.

CONNECTICUT

Grant for Work on Visual Functions.—The American Optical Company has given Yale University, New Haven, an additional grant in further support of the research program of the clinic of child development of the school of medicine. The grant covers the three year period 1945-1948 and finances investigations of the development of visual functions in the first ten years of life. The research work is being conducted on a cooperative basis by a medical and psychologic staff under the direction of Dr. Arnold L. Gesell, professor of child hygiene and director of the clinic of child development. Chief emphasis is being placed on problems of early diagnosis and of preventive control.

DISTRICT OF COLUMBIA

Seek Ban on Counter Sale of Sulfonamide Drugs.—The Medical Society of the District of Columbia on May 12 asked Dr. George C. Ruhland, health officer of the District, to ban all "over the counter sale" of sulfonamide preparations unless they are prescribed by a physician. The request came from the society's committee on public health, the chairman of which is Dr. Edward J. Stieglitz, and pointed out that "indiscriminate use of sulfa drugs sensitizes some individuals to an extent that they cannot later be benefited by use such drugs when they are badly needed," according to the Washington *Star*.

Lecture Named for Senator Sumner.—On May 24 the Medico-Chirurgical Society of the District of Columbia inaugurated the first annual Charles Sumner Lecture of the Medico-Chirurgical Society with a talk by Edmund V. Cowdry, Ph.D., professor and head of the department of anatomy, Washington University School of Medicine, St. Louis, on "The Present Status of the Problem of Cancer." The lecture will be given annually in honor of U. S. Senator Charles Sumner, who in 1869 was a champion of "equal rights and opportunities" for medical practitioners in the District of Columbia "without distinction of color." The Medico-Chirurgical Society was organized in 1884. Dr. W. Montague Cobb, professor of anatomy, Howard University College of Medicine, is president.

GEORGIA

Russell Oppenheimer Resigns as Dean.—Dr. Russell H. Oppenheimer has resigned as dean of Emory University School of Medicine, Atlanta, effective June 1, after holding the position for twenty years. After a leave of absence for rest, he will return to Emory to carry on his work as professor of clinical medicine. Dr. Eugene A. Stead Jr. will serve as acting dean in addition to his activities as professor of medicine and chairman of the department.

ILLINOIS

Abbott Science Club Affiliates with Sigma Xi.—On May 21 the Abbott Laboratories, North Chicago, Science Club became the first research group in the pharmaceutical industry to qualify for and be granted affiliation with the Society of the Sigma Xi, national honorary scientific society. Special ceremonies were held at the Georgian Hotel, Evanston, at which Michael Heidelberger, Ph.D., professor of biochemistry, Columbia University College of Physicians and Surgeons, New York, spoke on "Blood Complement."

Chicago

Dr. J. Gordon Wilson Retires.—Dr. John Gordon Wilson, professor and chairman of the department of otolaryngology, Northwestern University Medical School, since 1908, retired in April. Dr. Howard C. Ballenger, associate professor in the department, is now acting chairman.

Personal.—Comdr. James Roscoe Miller (MC), dean of Northwestern University Medical School, currently in charge of the section on internal medicine, professional division of the Bureau of Medicine and Surgery, Washington, D. C., has been appointed medical director of the Chicago and Northwestern Railway system, effective on his release from service and in addition to his activities as dean.

Alumni Banquet.—The annual banquet of the University of Chicago School of Medicine in honor of the graduating seniors is to be held at the Hotel Windermere, June 13. A scientific program preceding the alumni banquet will be held in the afternoon at Billings Hospital. Among the speakers will be:

Dr. Thomas F. Thornton Jr., The Mechanism of Citrate Intoxication.
Dr. William W. Scott, Urinary 17-Ketosteroids in the Diagnosis of Adrenal Cortical Carcinoma.
Dr. Francis B. Gordon, Studies in the Psittacosis Group of Viruses.
Dr. Peter P. H. DeBruyn, Locomotion Characteristics of White Cells.
Dr. Charles W. Eisele, Some Problems in the Diagnosis of Brucellosis.
Drs. James S. Clarke and Hilger P. Jenkins, "Gelatin Sponge"—A New Absorbable Hemostatic Agent.
William Burrows, Ph.D., Excretion of Antibodies in Feces of Immunized Animals.
Dr. Paul W. Schafer, Observations on the Etiology and Treatment of Polycythemia Rubra Vera.
Dr. Chauncey C. Maher, Significance of Presence of Q_3 and T_3 in Clinical Cardiography.
Dr. Morris E. Davis, Experimental Studies of Pigmentation of Endocrine Origin.
Drs. William E. Ricketts and Walter L. Palmer, Treatment of Generalized Peritonitis Complicating Ulcerative Colitis.
Dr. Henry T. Ricketts, Diabetes in a Totally Depancreatized Man.

INDIANA

State Council for Mental Health.—Governor Ralph E. Gates recently appointed five members to the Indiana Council for Mental Health, a group set up under 1945 legislation to develop the construction of a mental hospital and clinic on the campus of the Indiana University Medical Center in Indianapolis. Members of the council are Dr. LaRue D. Carter, professor of neurology; Dr. Thurman B. Rice, chairman of the department of bacteriology and public health and acting secretary of the state board of health, ex officio; Dr. Norman M. Beatty, Indianapolis; Judge John H. Morris, New

Castle, and Otto Walls, director of the state department of public welfare, ex officio. The 1945 general assembly appropriated $250,000 for the project and earmarked an additional $75,000 if needed. The hospital will be made available for instruction of medical students, student nurses, interns and resident physicians under the supervision of the medical school faculty. The council will have the authority to transfer psychiatric patients in state hospitals from one institution to another or to the so-called screening hospital on the Indiana University Medical Center Campus, admission to which will be open to voluntary applications on recommendation of attending physicians.

KANSAS

State Medical Election.—Dr. William M. Mills, Topeka, was chosen president-elect of the Kansas Medical Society at its meeting in Topeka, May 6, and Dr. William P. Callahan, Wichita, was inducted into the presidency. Other officers include Drs. Laurence S. Nelson, Salina, and Oscar W. Davidson, Kansas City, vice presidents; Franklin R. Croson, Clay Center, secretary; John L. Lattimore, Topeka, treasurer, and Forrest L. Loveland, Topeka, delegate to the American Medical Association.

Kansas Physicians' Service.—The Kansas Physicians' Service was formed in Topeka, May 5. Temporary officers chosen include Dr. Barrett A. Nelson, Manhattan, president; Dr. John L. Lattimore, Topeka, vice president; Dr. William M. Mills, Topeka, secretary-treasurer, and Mr. Oliver E. Ebel, Topeka, executive vice president. Within sixty days a permanent board of directors will be elected, after which the final preparations will be made and the sale of the benefits of the medical service plan will be started through the Blue Cross.

NEW YORK

Chiropractors Urge Passage of Murdock Bill.—The executive committee of the New York State Chiropractic Society at a meeting in Binghamton, May 20, passed a resolution favoring the passing by congress of the Murdock bill, which would amend the U. S. Compensation Act and which calls for the inclusion of the services of chiropractors when desired by federal employees injured in the line of duty, according to the Rochester *Democrat and Chronicle.*

Personal.—Dr. Donald M. Morrill, Malden, Mass., has been appointed chief administrative officer of the Mount Vernon Hospital, Mount Vernon, effective April 1.——Dr. George Y. McClure has been appointed director of the Westchester Department of Laboratories and Research, succeeding Dr. Gilbert Dalldorf, who took over a similar position for the state department of health (THE JOURNAL, April 28, p. 1139). Dr. McClure has also been named pathologist at Grasslands Hospital, Valhalla, where he has been serving as assistant pathologist.——Dr. William J. Carr, Newburgh, recently completed fifty years in the practice of medicine. From 1897 to 1904 he was health officer of Newburgh.——Dr. John G. Ellis, Albion, has been appointed coroner of Orleans County, succeeding the late Dr. Paul H. Mahany, Albion.——Dr. Robert C. Towse, White Plains, has been appointed medical director of the Rensselaer plant of the Winthrop Chemical Company.

New York City

Gustave Meyer Dies.—Gustave M. Meyer, D.Sc., associate chemist on the staff of the Rockefeller Institute for Medical Research, died near Saranac Lake, May 9, aged 69. Dr. Meyer had been associated with the Rockefeller Institute from 1909 to 1941, when he retired.

Squires Prize Goes to Army Physician.—Capt. George Rosen, M. C., Brooklyn, has been awarded the Grant Squires Prize for his book "The History of Miners' Diseases: A Medical and Social Interpretation." The prize is given every five years to a graduate of Columbia University for original investigation of a sociological nature. The presentation was to be made at Columbia's commencement exercises June 5.

Teachers Union Condemns Protest on Tuberculosis Tests.—The teachers' union on May 24 issued a statement condemning the Joint Committee of Teachers Organizations for its recent action in sponsoring a lawsuit against the board of education regulation requiring the teachers to take chest x-ray examinations for tuberculosis (THE JOURNAL, June 2, p. 378). The statement in addition urged extension of the examination to all pupils as well, according to the New York *Times.*

City Cooperates in Proposed Tropical Medicine Center.—A tentative agreement was signed by Mayor Fiorello La Guardia May 14 committing the city to share in the $5,390,000 hospital and health center for the study and treatment of tropical and communicable diseases to be built on land conveyed without cost to the city by Columbia University and Presbyterian Hospital. According to the New York *World-Telegram* the site extends 800 feet along the west side of Riverside Drive between 165th and 168th streets. The proposed center includes a 300 bed hospital and a research building which will house a diagnostic laboratory of the health department, a research center for the city sponsored Public Health Research Institute (THE JOURNAL, July 12, 1941, p. 128) and a specialized branch operated by the Columbia University College of Physicians and Surgeons.

OHIO

Cleveland Hearing and Speech Center.—The Cleveland Hearing Center and Speech Clinic at Western Reserve University have formed the Cleveland Hearing and Speech Center, Inc., and will establish quarters at 11206 Euclid Avenue on the university campus in the fall or as soon as the release of material and labor for remodeling permit. The new organization will greatly augment the present care for Cleveland men, women and children with speech and hearing difficulties. The name "Garfield House" will be retained for the new unit, carrying on the project established in 1924 by the late Mrs. Garfield, wife of James R. Garfield, who is chairman of the board of the new center and president of Garfield House, 8917 Euclid Avenue, where the hearing center is now situated. The new center will absorb all the activities of Garfield House, social, educational, recreational, preventive and guidance, and will expand the work of the speech clinic in treatment, in training of teachers and therapists and in research. Lowell C. Ruch, executive director of Garfield House for the past ten years, will be the director of the new hearing and speech center. A chief of services for the center will be announced later. He will hold this position and that of professor on the faculty of Western Reserve University and be in charge of the new appliance laboratory to be established at the center. The new quarters, consisting of twenty-five rooms on three floors and a basement, will be remodeled completely and contain classrooms, examination rooms, cubicles for individual hearing and speech therapy, appliance laboratory, research laboratory, library, club rooms and recreation rooms for children. Members of the staff will include:

Miss Amy Bishop, director of the speech clinic at Western Reserve, assistant to the chief of services.

Miss Genevieve Garrison, senior therapist, clinical director of speech service.

Miss Ruth Lundin, therapist and director of the speech treatment of the Cleveland Rehabilitation Center, director of the student's laboratory.

Dr. Julius W. McCall, demonstrator in anatomy, Western Reserve University School of Medicine, in charge of the laryngectomy work.

Mrs. Florence Fross, assistant to Dr. McCall at the speech clinic, who will give speech instruction to persons who have had their larynxes removed.

C. A. Buchholz, who will give additional instruction in speech to stutterers.

Miss Virda L. Stewart, president of the Women's City Club of Cleveland and instructor in English and speech at Cleveland College, who will give speech instruction to those with foreign accents.

Clifford Mohan and Miss Dorothy Kester of the Alexander Graham Bell School of Cleveland, who will serve as part time specialists in lip reading.

PENNSYLVANIA

County Society Observes One Hundredth Anniversary.—The Schuylkill County Medical Society observed its one hundredth anniversary in Pottsville, June 6, with a special program in conjunction with the annual meeting of the third, fourth and twelfth councilor districts. Among the speakers were:

Capt. William M. Webb, M. C., Recent Diagnostic Problems in the Tropics.

Mr. Lester H. Perry, Harrisburg, executive secretary, state medical society, Medical Service Association of Pennsylvania.

Dr. James Stratton Carpenter, Pottsville, The One Hundredth Anniversary of the Schuylkill County Medical Society.

Dr. John J. Walsh, Pottsville, Recent Trends in Our Knowledge of Coronary Sclerosis and Their Influence on the Clinical Management of These Patients.

Dr. Walter F. Donaldson, Pittsburgh, secretary-treasurer, state medical society, Welcome Home, Soldier!

Dr. Chauncey L. Palmer, Pittsburgh, Highlights of the 1945 Legislature.

A feature of the meeting was the presentation of fifty year testimonials by Dr. William L. Estes Jr., Bethlehem, president-elect, state medical society, to Drs. Arthur J. Bird, New Albany; William G. Berryhill, Orangeville; Allan C. Brooks, Wilkes-Barre; Clinton J. Kistler, Lehighton; J. Warren Knedler, Moscow; Herbert B. Gibby, Wilkes-Barre, and Edward S. Rosenberry, Stone Church.

Philadelphia

Portrait of Dr. Bauer.—Dr. Edward L. Bauer, professor of diseases of the child, Jefferson Medical College of Philadelphia, was honored recently by the senior class when a portrait of him was presented to the medical school. The program was in charge of Mr. James H. Lee Jr., president of the senior class, and speakers included Robert C. Puff, senior, Dr. Norman M. MacNeill, who made the presentation speech, and Dr. William Harvey Perkins, dean, who gave the speech of acceptance. Dr. Bauer also spoke.

Survey of Psychiatric Clinics.—Under a grant from the Seybert Institution, the Philadelphia Council of Social Agencies is engaged in surveying the psychiatric clinics of Metropolitan Philadelphia with a view to planning for postwar expansion of such services. A committee representative of the clinics and organizations interested in psychiatric services for children is supervising the study, which is being conducted by several psychiatric social workers under the direction of Helen L. Witmer, Ph.D., of the Smith College School for Social Work, according to *Philadelphia Medicine*.

Pittsburgh

The Mellon Lecture.—John R. Murlin, Ph.D., professor of physiology and director of the department of vital economics at the University of Rochester School of Medicine and Dentistry, gave the twenty-eighth Mellon Lecture of the Society of Biological Research of the University of Pittsburgh School of Medicine, May 16. His subject was "Biologic Value of Proteins in Relation to the Essential Amino Acids."

TEXAS

Personal.—Dr. John N. Thomas, Mansfield, was recently guest of honor at a dinner celebrating his eighty-eighth birthday and fifty-sixth year of service in Mansfield and the surrounding area. In 1943 Dr. Thomas was honored by the Business and Professional Women's Club of Mansfield as the outstanding citizen of the community.——Dr. William W. Coulter, acting superintendent of the Jefferson Davis Hospital, Houston, has been named medical director of the hospital. The action marks a departure in the administrative setup. A. S. Reeves, Quanah, has been designated superintendent.

Medical Library Banquet.—On May 18 a banquet was held at the Adolphus Hotel to provide additional funds for the library of Southwestern Medical College. The affair was known as the "Medical Library Banquet" and was sponsored jointly by the Dallas County Medical Society, the Dallas County Dental Society, Dallas County Pharmaceutical Association, Medical Service Society of Dallas, District Number 4 Texas Graduate Nurses Association, Dallas County Dental Assistants, the Dallas Hospital Council and the women's auxiliaries of the respective organizations. It is hoped to make the affair annual.

Control of State Psychopathic Hospital Transferred.—The legislature of the state of Texas has unanimously authorized the transfer of the Galveston State Psychopathic Hospital from the State Board of Control to the Board of Regents of the University of Texas to be operated as a part of the Medical Branch. Formerly accommodating approximately 80 patients, the institution will be reequipped to handle about 120 mental patients for rapid diagnosis and rapid treatment. Special facilities will be provided for postgraduate training in neuropsychiatry and for psychiatric nurse training. The director is Dr. Jack R. Ewalt, associate professor of neuropsychiatry, University of Texas School of Medicine. The hospital will not be ready to receive patients until refurnishing and reorganization have been completed.

WEST VIRGINIA

Changes in Health Officers.—Dr. James A. Dolce, Fairmont, has resigned as health officer of Marion County, effective April 23. Dr. Claude A. Thomas, who has been serving as health officer of district number 4, comprising the counties of Lewis, Calhoun, Gilmer and Upshur, during the absence because of illness of Dr. Walter J. Riley, Weston, has been transferred to Romney, where he will be in charge of district number five including the counties of Hardy, Grant, Hampshire, Mineral and Morgan. Dr. Riley has returned to his activities in district number 4.

Decrease in Cancer Deaths.—Deaths from cancer in West Virginia in 1944 totaled 1,525, according to provisional figures compiled by the division of vital statistics of the state department of health. The totals represent a decrease of 97 in deaths from the disease as compared with the figure for 1943, when the total was 1,622. The estimated death rate in West Virginia from cancer per hundred thousand of population in 1944 was 88.9, compared with 92.4 in 1943. Using the basis of 4 living persons with cancer for every death, there are approximately 6,100 cases of cancer in West Virginia at the present time. The services of the division of cancer control have been extended to 560 cancer patients needing assistance in financing treatment and care.

WISCONSIN

Public Park Named for Physician.—Dr. Thomas G. Torpy, Minocqua, was honored May 30, when a public park in the town was dedicated to him and which in the future will be known as the Doctor Torpy Park. Dr. Torpy graduated at Rush Medical College in 1895, and the recent honor was in recognition of his completion of fifty years in the practice of medicine, most of which have been spent in Minocqua. Among the speakers at a testimonial dinner were Gerald Boileau, Wausau, formerly national representative to congress, and Dr. Edward L. Jenkinson, Chicago. Dr. Torpy was chairman of the board of supervisors for a number of years. Grade school children presented Dr. Torpy with a bond and the people of the community with a purse of $2,000.

Program Honors Retiring Professors.—The faculty of the University of Wisconsin Medical School, Madison, held a special program May 15-16 to mark the retirement of Drs. Charles H. Bunting, professor of pathology, and Joseph S. Evans, professor of medicine, University of Wisconsin Medical School. Dr. Bunting was the first professor of pathology at the medical school, joining the university in 1908; he is also chairman of the department. Dr. Evans, who began his affiliation in 1909, was the school's first professor of medicine. He is also chairman of the department. As a special feature of the program, Dr. Eugene L. Opie of the Rockefeller Institute for Medical Research, New York, spoke on "Production Tumors, with Special Reference to Hepatic Tumors Produced by Feeding Azo Compounds" and "Significant Questions Concerning Transmission and Epidemiology of Tuberculosis."

GENERAL

College of Radiology Moves.—The American College of Radiology has moved its headquarters from 540 North Michigan Avenue to 20 North Wacker Drive, Chicago 6.

Examinations in Pediatrics.—The American Board of Pediatrics announces that its fall written examination will be held locally under a monitor, October 19. The oral examination will be held in New York, December 7 or 8. Dr. C. Anderson Aldrich, 115½ First Avenue S.W., Rochester, Minn., is secretary of the board.

Home Study Courses.—The Home Study Courses sponsored by the American Academy of Ophthalmology and Otolaryngology, in the basic sciences of those two specialties, will be given again in the year 1945-1946. Registrations must be completed before August 15. For information apply to Dr. William L. Benedict, executive secretary, 100 First Avenue Building, Rochester, Minn.

Charles Stephenson Succeeds Clarence Little.—Rear Admiral Charles S. Stephenson (MC), U. S. Navy, retired, has been appointed acting managing director of the American Cancer Society. He will succeed Clarence C. Little, Sc.D., Bar Harbor, Maine, who will direct studies of genetic factors of intelligence and emotional variations in mammals under a Rockefeller Foundation grant (THE JOURNAL, June 2, p. 379). Admiral Stephenson was named some months ago as secretary of the research division of the cancer society (THE JOURNAL, April 7, p. 936). Dr. Little will continue as a member of the society's board of directors.

Prevalence of Poliomyelitis.—The National Foundation for Infantile Paralysis announced June 1 that the number of poliomyelitis cases in the country is running about 50 per cent ahead of a year ago. As of mid-May, the number of new cases this year were 642 as compared with 424 cases for the same period in 1944. Sharp increases have been reported in the New England states, Middle Atlantic states, South Atlantic area and the East South Central states. In the Pacific Coast and West South Central areas, which have been hard hit during the past two years, there has been a noticeable drop in the number of new cases. In the remainder of the country there are about the same number as last year. While a fact that there are 50 per cent more cases in the country this year than in the same period in 1944, "this is not an alarming situation but it should be watched carefully," it was stated.

The foundation has available a bulletin entitled "When Polio Strikes" which includes many helpful hints for parents and contains a series of simple precautions to be taken during the summer months.

Examination in Obstetrics and Gynecology.—The general oral and pathology examinations of the American Board of Obstetrics and Gynecology (part II) for all candidates will be conducted at the Shelburne Hotel, Atlantic City, N. J., by the entire board June 13-19. Hotel reservations may be made by writing directly to the hotel. The Office of the Surgeon General of the U. S. Army has issued instructions that men in service, eligible for board examinations, be encouraged to apply and that they may request orders to detached duty for the purpose of taking these examinations whenever possible. Candidates in military or naval service are requested to keep the secretary's office informed of any change in address. Deferment without time penalty under a waiver of published regulations applying to civilian candidates will be granted if a candidate in service finds it impossible to proceed with the examinations of the board. Applications are now being received for the 1946 examinations. For further information and application blanks address Dr. Paul Titus, secretary of the board, 1015 Highland Building, Pittsburgh 6.

PUERTO RICO

Survey of Schistosoma Infections in Snails.—The School of Tropical Medicine, San Juan, has instituted a study of current percentages of Schistosoma infections in snails under the direction of Dr. Pablo Morales Otero, San Juan. According to an announcement, schistosomiasis was diagnosed in 12.4 per cent of the population in Puerto Rico in 1934, and snails removed from the Barranquitas River in that year were 28 per cent infected with the disease. Today, says the announcement, the infection index is 80 per cent and there is every reason to believe that the incidence in the population in general is much higher. The army would not accept any man from Puerto Rico who has a history of schistosomiasis. It is believed that the study of the School of Tropical Medicine will serve to incite programs to control the disease.

Actions by the Governor.—Governor Rexford G. Tugwell signed a bill passed by the legislative assembly of Puerto Rico appropriating the sum of $500,000 from insular funds to continue the construction, extension and repair of the Insular Hospital of Psychiatry. The governor also signed a bill appropriating the sum of $315,000 from insular funds to construct and equip an Insular Home for Girls in the city of San German, which will function under the auspices of the department of health of Puerto Rico. An application made by Laboratories Terrier, Inc., of Hato Rey, San Juan, for tax exemption was denied by the governor. This firm makes ampules for hypodermic injections. Tax exemption for this company, granted by the public service commission of Puerto Rico for three years by a resolution passed June 7, 1944, was disapproved by the governor.

LATIN AMERICA

Health Activities in Latin America.—*Radio Scripts on Health.*—The medical section of the Health and Sanitation Division of the Office of the Coordinator of Inter-American Affairs has started the preparation of radio scripts on disease and health as a contribution to the programs of health education by radio. According to the *Newsletter* of the Health and Sanitation Division this radio material so far has been sent out by the radio division on microfilm and in Spanish and Portuguese but is available in typewritten form in English. The scripts are produced for the health and sanitation field parties, the coordination committees and any other groups that wish to use them. They need not, of course, be restricted to the radio but may be brought out as pamphlets or put to other uses. The first six scripts prepared under this project dealt with the health of the baby and young child and covered the topics of cleanliness, nutrition, feeding habits and immunization against diphtheria, smallpox and whooping cough. A series of five scripts on tuberculosis has just been completed. These are written as a family drama, but each is a unit in itself so that a person hearing only one would gain information on the transmission of tuberculosis and his personal defense against it. The five scripts on tuberculosis are entitled "The Symptoms," "The Health Center," "The Nursing Visit," "The Contacts" and "The Sanatorium." In some countries it will be possible to use these scripts without any modifications. In other countries, characterizations and scenes may need revision to satisfy local needs.

Treatment of the Lepros.—Children born of leprous patients in the Palo Seco Leper Colony on the west back of the Pacific entrance to the Panama Canal are free of leprosy, the health department of the Panama Canal reports. Progenitorship, however, ends with birth. Forfeiture of parental possession becomes effective immediately after parturition. Parents are forbidden to touch the offspring. The infants are promptly removed from the leprous environment of their birth. Permanent separation from leprous parents is achieved through adoption into the homes of relatives. To date, according to the health department, not a single case of leprosy has occurred among the adopted children. Communication of infection from husband to wife or wife to husband is uncommon. Though housed in different buildings, men and women patients are free to associate during the day. The resultant romances are not obstructed by the colony management. When these courtships develop into matrimonial aspirations, official consent of marriage is rarely withheld. The routine offers of sterilization are usually rejected on religious grounds. Two room apartments with kitchen, toilet and bathing facilities are provided for married couples. Established in 1907, the Palo Seco colony covers a 500 acre tract chosen by the late Col. William C. Gorgas. The colony's housing facilities consist of eight modern two story structures built in a quadrangle near the beach.

Visitors to the United States.—Dr. Luiz Mendonca e Silva, who was employed in the office of health education in the state health department in Rio de Janeiro, is studying currently at the DeLamar Institute of Public Health, Columbia University, New York. On conclusion of the course he will spend some time at the headquarters of the American Medical Association, Chicago.——Dr. Rodolfo Mascarenhas, São Paulo, Brazil, assistant to the director of the state health department, who has been studying public health administration as a guest of the state department, visited the American Medical Association, May 7.——Dr. Henrique de Rocha Lima, director of the biologic research institute of São Paulo, Brazil, is in the United States as the guest of the department of state to confer with scientists and technicians specialized in agricultural, microbiologic and pathologic research. Dr. Rocha Lima was once professor of tropical medicine at the University of Hamburg, Germany.

Cancer Stamp.—Commemorating the fight for the conquest of cancer, four million one cent postage stamps bearing the picture of the late Pierre and Madam Marie Curie will be issued by the government of Panama, the minister of government and justice announced.

Hospital News.—A maternity hospital for nonpaying patients has been opened by the government of Barbados, British West Indies, at Bank Hall. The Colonial Development and Welfare contributed $115,200 toward the project.

Government Services

New Regional Director for Children's Bureau

Dr. John F. Belz, Portland, director of the maternal and child health division of the Oregon State Board of Health, has joined the staff of the division of health services, Children's Bureau, U. S. Department of Labor, to serve as regional medical director in the Rocky Mountain area, comprising the states of Colorado, Wyoming, Montana, Idaho and Utah. For the present the offices will be located at 1505 Humboldt Bank Building, 785 Market Street, San Francisco 3.

National Institute of Health Research Fellowships

The Public Health Service announces the creation of National Institute of Health research fellowships, available after July 1. The junior research fellowships will be to those holding masters degrees in the sciences (such as physics, chemistry and entomology) allied to public health from an institution of recognized standing. The stipend will be $2,400 a year. The senior research fellowships will be available to those holding a doctorate degree in one of the sciences allied to public health. The stipend will be $3,000 a year. These fellowships will offer an opportunity for study and research in association with highly trained specialists in the candidates' chosen field at the institute or some other institution of higher learning. Letters of inquiry should be addressed to the director, National Institute of Health, Bethesda 14, Md.

Foreign Letters

LONDON

(From Our Regular Correspondent)

May 5, 1945.

Resettlement Camps for Homecoming Prisoners of War

The army is establishing all over the country voluntary camps for homecoming prisoners of war discharged or released from the service. These will be centers where men may acclimatize themselves to social surroundings, which, after long absence and the constraints of life in prison camps, may well at first be strange. The camps will be known as civil resettlement units and will be situated in pleasant surroundings near to towns, with their industries and their social services, and a man who chooses to go will naturally select one near his home. The camps will be a starting off point for a return to the civilian life from which the men have long been estranged. Run like a leave camp, they will be free from "training" in the military sense, and there will be only one parade—the pay parade. The means for putting the men in touch with civilian life again include films and talks on what has been going on in their absence, visits to places of importance to those anxious to regain their footing in the ordinary ways of life, and advice by qualified persons on future employment, pay, health, and personal and family affairs.

A man's only duty will be to keep his bed and his belongings tidy. There will be no reveille, no guards, no fatigues. A man will more or less arrange his own day, choosing between a visit to a factory or technical school, an office or a training center or spending part of his time in a workshop rehandling tools or attending a discussion. During these working hours he will wear a uniform but afterward, whether he remains in the camp or goes out, he can change to civilian clothes. There will be leave every week end for those who want it. To vary the day's events there will be light physical exercises and optional games.

A pamphlet is given to all homecoming prisoners of war telling them that "changes have taken place in 'civvy street.' There are ration cards and wartime regulations. You have changed too. You have seen new countries and different people. You have a new outlook on civilian life and possibly a better one. But you will need time to find your feet again." In deciding on a new job, the man will receive specialist advice.

Cholera Epidemic in Calcutta

An unusually severe epidemic of cholera in Calcutta is causing concern to the army command in India. Most of the sufferers are civilians, but there are some suspected cases among soldiers. During the week ended April 21 there were two hundred deaths in the city from cholera. The seriousness of the situation lies in the fact that, besides being important as a military base, both British and American, Calcutta is perhaps the greatest transit and leave center for troops of the allied land forces in southeastern Asia. The severity of the epidemic is attributed to the general overcrowding, the filthy living conditions in the slums and the absence of a decent standard of cleanliness in any part of the city. Administration by the elected corporation of Calcutta has been slack for years, with the result that a situation has developed which it cannot remedy with the equipment and men available. There were occasions when the Bengal ministry seemed to be on the point of dismissing the corporation, but this would not now remedy the lack of equipment. The important Indian newspaper the *Statesman* says that the immediate needs are drastic administrative control of dirty markets, abolition of the exposure of fruit for sale and its sprinkling with foul water, control of the use of ice in beverages, prevention of the display of eatables on curb side stalls and clearance of beggars from the streets. To the might be added regular and thorough emptying of garbage can and the removal of cattle from the streets.

The High Cost of Industrial Accidents

High estimates of the cost of industrial accidents were give by Mr. Bevin, minister of labor, and Sir Wilfred Garret chief inspector of factories, to a largely attended conference o industrial accidents held in London. Mr. Bevin said that th cost of workmen's compensation was $87,500,000 a year, bu this was computed to be only a fifth of the total loss to th community. When they took into account the hidden costs i the form of loss of production, loss of time of other employee: when an accident disturbed the smooth working of the shop damage to machinery and plant, loss of material and the like they could see how the estimate would grow to a total cost o something like $350,000,000 a year. Referring to the human loss, it was impossible to measure what the accidents repre sented in broken lives. Much assistance would be given by the government's new scheme of rehabilitation, but better than rehabilitation was prevention. Training in all directions—training of accident prevention officers and training of a works safety committee. The following figures were given by the chief inspector of factories. Every year 1,000 workers are killed in factories, 800 in mines and between 6,000 and 7,000 on the roads. In addition there is all the loss due to nonfatal accidents.

Victoria Cross for Member of the Army Medical Corps

The Victoria Cross is the most coveted award in the British army and is gained only by the most conspicuous bravery, often at the cost of life, so that it has to be posthumously given to a relative. The king has approved the posthumous award to Lance Corporal Henry Eric Harden, Royal Army Medical Corps. In northwestern Europe on January 23 the leading section of a Royal Marine commando troop was pinned to the ground by intense enemy machine gun fire from well concealed positions and was ordered to take cover. But 4 wounded men were lying in the open. Harden at once went forward under a hail of machine gun and rifle fire directed from four positions, all within 300 yards. With the greatest coolness and bravery he remained in the open while attending the casualties. After dressing the wounds of 3 he carried 1 man back to cover. He was ordered not to go forward again but did so with a volunteer stretcher party and brought back another badly wounded man. He went a third time with a stretcher party and was bringing back a wounded officer when he was killed by heavy enemy fire. His courage saved the lives of the wounded brought in and was an inspiration to the others. In Parliament Sir James Grigg, secretary of state for war, said "I do not remember ever reading anything more heroic."

Successful Transport by Air of the Wounded

It is now possible to give figures of the transport by air of the wounded in Normandy, Arnhem and the Rhine crossing. This was performed by the Transport Command group of the Royal Air Force responsible for carrying supplies from Britain to the continent of Europe. Since D day it has carried to the continent a monthly average of 1,600 tons of freight and brought back 241 tons of mail, besides an average of about 1,000 passengers. In that period it also brought back to England 70,000 casualties and transferred 22,000 more from advanced landing strips to base hospitals in liberated territory. Not one "hospital" aircraft has met with a mishap. When the fighting was in France and Belgium it was common for men wounded in the morning to be operated on in an English hospital the same evening.

The Definition of Medicine

French medicine is in a state of crisis and is to be developed along the patterns furnished by foreign countries, especially the United States and Russia. The traditional boundaries of the profession seem too narrow; under the name of social medicine there is a universal desire for an extension of the activity of the physician and his domain, corresponding to the ever widening sphere which medicine plays in the collective life. Medicine of tomorrow will come out of its restricted scientific limits to assume a broader purpose and penetrate more intimately into human institutions. That is the ambition of most physicians and of practically all sociologists.

A symbol of this desired extension of the medical art is the fusion under the direction of Charles Claoué, well known for his work on esthetic surgery, of two independent institutions which complete the education of the physician and that of the sociologist: the Institut de sociologie and the Ecole libre des sciences médicales. According to Claoué, medicine will be, in the last analysis, the study of relations between man and animal (veterinary medicine), man and plants (botanic medicine), between man and the external or internal environments in which he lives (human medicine), in all the cases in which the desirable harmony of interrelations is disturbed. Many other professions besides that of the physician are charged with the improvement of these relationships, but they cannot accomplish their mission in working alone, and all have need to know and to collaborate with one another. A psychologist is a physician who must know man in sickness as well as in health. A legislator is concerned with the possibilities and impossibilities of social life; a pedagogue cannot ignore the limits of health and the growth of the child, an architect must build only sanitary houses, an economist has the chief aim of furnishing man with wholesome food.

According to the principles proposed by Claoué, the free school of medical sciences has the program to define medicine and its new duties, to furnish to all the professions which have medical aspects the knowledge which they need. The Ecole libre des sciences médicales has the aim to complete the education of the physician as well as to furnish to the different professions the indispensable supplementary medical education.

Medical Research in France

In a recent conference which was published in the *Médecin français*, Raoul Kourilsky of Paris exposed the shortcomings and difficulties of medical research in France. Kourilsky believes that the clinical level of French medicine has been maintained but that its scientific level has not ceased to decline for the last twenty years. He believes that the decay or stagnation is due to the fact that the present organization of research does not permit the investigator to give his full effort at a time when the conditions of work are more difficult than they have ever been. It is by research that a nation maintains its intellectual influence; to limit oneself to utilize the discoveries of others means, to quote Jolliot-Curie, "to be resigned to become the equivalent of a colony."

There are two types of research: scientific research with medical applications and direct medical research. The scientific researches with medical applications are pursued without initial medical aim, but they end by finding so much reverberation and so much application in medicine that they become a part of it. Kourilsky cites two essentially French discoveries: the anatoxins (toxoids) and the isolation of paraminophenylsulfamide, which are not strictly medical but which have become so. They show what could be achieved in France, if France had more investigators and more laboratories and especially if these laboratories worked in better and organized cooperation and not in occasional and incidental collaboration with the medical centers where their discoveries are applied.

As regards the specific medical investigations generally carried out by physicians in contact with patients, they should not be confused with the many verifications which are required every day in the practice of medicine and which, moreover, are difficult to obtain in a regular and exact manner even in the faculty cities. These verifications apply most of the time to isolated cases. They can serve research, but, as Kourilsky says, they do not represent that "first time."

If French medicine is to recover its prestige, it is necessary to create a framework for it, to open a career to the scientist, which assures a satisfactory budget for the workers. It is necessary that life in the hospital becomes a habit. The individual laboratories must be juxtaposed with the great scientific research centers. A certain number of physicians must be able to live with the sole preoccupation of the advancement of science. These truths were good to repeat to the French, who only have to turn their attention toward their neighbors to know why France has been surpassed in the glory of discovery and what must be done to recover the lost position.

Duodenal Aspiration

In a report presented before the Société de chirurgie de Lille Decloux analyzed 59 cases in which duodenal aspiration was employed for the treatment of intestinal obstruction. Twenty-seven of these cases involved primary obstruction, developing either in a subject already operated on (late postoperative obstruction by adhesions, angulations and the like) or in a new subject. It is necessary to consider that aspiration can only have slight action in obstructions of the large intestine, which are easy to diagnose from roentgenologic and clinical signs. But it is less easy to differentiate between simple obstruction by tumor, biliary ileus and adhesions, in which aspiration does wonders, and the strangulation by volvulus, internal constriction and so on, where it is dangerous for the intestinal vitality. In general, duodenal aspiration will be advisable when strangulation is probable; this menace will be indicated by a very acute onset, by the continued, nonintermittent character of the pains, recalling the syndrome of Koernig, by moderate distention and especially by x-ray examination, which will show an isolated loop completely dilated. In the other cases the rapid deflation of the abdomen, verified immediately by roentgenologic control, after the putting in place of the aspirating tube, facilitates greatly diagnosis and surgical intervention, and as a result the operative mortality will be greatly reduced.

Marriages

GORDON JEROME STREWLER, Racine, Wis., to Miss Effie Elizabeth Pressly of Chester, S. C., at Louisville, Ky., April 27.

HOWARD CARRINGTON, Onarga, Ill., to Miss Lucy Jane Hooker of Lebanon, Mo., in Camp Anza, Calif., recently.

MARION F. ARNOLD Jr., New Palestine, Ind., to Miss Kathryn Costellow of Beech Grove in Indianapolis, March 21.

ARTHUR HERRMANN DOWNING, Des Moines, to Miss Mary Elizabeth Sayre at Fort Snelling, Minn., recently.

DAVID RICHARD PICKENS JR., Nashville, Tenn., to Miss Harriet Palmer of Montclair, N. J., May 12.

OSCAR DAVIS RATNOFF, New York, to Miss Marian Foreman in San Antonio, Texas, March 31.

JOE D. COMBS to Miss Fay Meshew, both of Muncie, Ind., in Lewisburg, Ohio, March 1.

WENDELL A. JOHNSON, Iowa City, to Miss Joan Chance of Redfield, April 21.

PAUL L. LONG to Miss Helen Stahlsmith, both of Anderson, Ind., February 26.

Deaths

James Thomas Nix ⊕ New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1910; clinical professor of surgery at the Louisiana State University School of Medicine; served as dean, director, professor and head of the department of surgery at the Louisiana State University Graduate School of Medicine; for many years professor of general surgery at the Loyola University School of Dentistry; professor of surgery at the Loyola University Post-Graduate School of Medicine from 1916 to 1918; in 1930 received the Medical Records Prize of the American College of Surgeons; fellow of the Southeastern Surgical Congress; member and for many years medical adviser, Catholic Hospital Association; member of the National Gastroenterological Association, Southern Medical Association, New Orleans Post-Graduate Medical Assembly and the Société Internationale de Gastro-Enterologie; in 1939 member of the International Cancer Congress; past president of the Catholic Physicians Guild of New Orleans, served as first and second vice president of the Louisiana State Medical Society, vice president and president of the Orleans Parish Medical Society; honorary member of the Illinois Clinical Club, the Seventh District Medical Society and Lafourche Valley Medical Society; first lieutenant, medical reserve corps, U. S. Army, 1918-1919; served at various times as director of the J. T. Nix Clinic, senior surgeon, and director of the Oscar Allen Tumor Clinic, Charity Hospital and senior surgeon, and president of the Hotel Dieu; in 1936 first exhibitor selected for Hall of Science for his subject on cancer; since 1942 medical director of the Higgins Industries and Higgins Corporation; in 1937 chairman of the honorary advisory committee of the Louisiana State Hospital Board and in 1938 chairman of the health committee of the eighth National Eucharistic Congress; in 1929 decorated Knight of St. Gregory and in 1930 Knight Commander of Holy Sepulchre; member of the founders group of the American Board of Surgery; in 1924 received the honorary degree of doctor of laws from Loyola University; author of "The Unborn," "A Surgeon Reflects" and two books of poems; died May 17, aged 57.

Edgar Garrison Ballenger ⊕ Atlanta, Ga.; University of Maryland School of Medicine, Baltimore, 1901; member of the House of Delegates of the American Medical Association in 1912; president of the Southern Medical Association, serving as member of the council from 1934 to 1939; served as president of the Fulton County Medical Society in 1911; made president of the Southeastern section of the American Urological Association in 1934-1935 and president of the association in 1938-1939; in 1930 first president of the Southeastern Surgical Congress, which he was instrumental in organizing; fellow of the American College of Surgeons; specialist certified by the American Board of Urology, Inc.; during World War I served in France with the rank of captain and with the Emory Base Hospital unit; later transferred to the 26th Division as urologist and remained with this division for eight months; promoted to major and remained in Germany two and one half months with the Army of Occupation; formerly associate professor of surgery (genitourinary) at the Emory University School of Medicine and lecturer on genitourinary diseases and syphilis at the Atlanta School of Medicine; consulting urologist at the Grady Hospital and urologist at the Crawford W. Long Memorial Hospital; author of "Genito-Urinary Diseases and Syphilis" and contributor to section on diseases of the urethra for the Oxford Loose Leaf Surgery; at one time associate editor and assistant manager of the *Atlanta-Journal Record of Medicine* and on the advisory editorial board of the *Southern Surgeon;* died June 1, aged 67, of injuries received in a seven floor fall to the mezzanine of the hotel where he had been residing.

William Worthington Herrick ⊕ New York; Yale University School of Medicine, New Haven, Conn., 1905; professor of clinical medicine at the Columbia University College of Physicians and Surgeons; specialist certified by the American Board of Internal Medicine; president of the New York Academy of Medicine; member of the Association of American Physicians; fellow of the American College of Physicians, of which he had formerly been regent; a major in the medical corps of the U. S. Army during World War I, serving for two years as chief of service and medical consultant at the Army Base Hospital in Columbia, S. C.; internist, medical advisory board of the Selective Service; attending physician at the Presbyterian Hospital and Sloane Hospital for Women; consulting physician, Beekman Street, Women's and Babies hospitals, all in New York, Mary McClellan Hospital, Cambridge, N. Y., Vassar Brothers Hospital, Poughkeepsie, Elizabeth A. Horton Memorial Hospital, Middletown, N. Y., Mount Vernon (N. Y.) Hospital, Goshen (N. Y.) Hospital, St. Agnes and White Plains hospitals, both in White Plains, N. Y., Stamford (Conn.) Hospital, Sharon (Conn.) Hospital, Greenwich (Conn.) Hospital and Nassau Hospital in Mineola, N. Y., and New York Infirmary for Women and Children; member, board of trustees, Trudeau Sanatorium, Trudeau, N. Y.; editor-in-chief, Nelson New Loose-Leaf Medicine; found dead June 1, aged 66.

Charles Terrell Porter ⊕ Boston; University of Virginia Department of Medicine, Charlottesville, 1912; lecturer on otology at the Harvard Medical School; specialist certified by the American Board of Otolaryngology; member and formerly vice president of the American Academy of Ophthalmology and Otolaryngology and the American Laryngological Association; member of the American Laryngological, Rhinological and Otological Society, American Otological Society, Inc., and the New England Otological and Laryngological Society; fellow of the American College of Surgeons; served with the Harvard medical unit attached to the British army in France during World War I; chief of the otolaryngology and rhinology staff, Waltham (Mass.) Hospital; consulting otolaryngologist, Cambridge (Mass.) Hospital and the Emerson Hospital, Concord; otolaryngologist, Burbank Hospital, Fitchburg; surgeon to the Massachusetts Eye and Ear Infirmary and the Massachusetts General Hospital; chief otolaryngologist to the Robert Breck Brigham Hospital and the Massachusetts Women's Hospital, where he died April 19, aged 56, of coronary thrombosis.

William Presley Dingle ⊕ Colonel, U. S. Army, retired, Mission, Texas; Illinois Medical College, Chicago, 1908; completed the courses at the Army Medical School and Medical Field Service School; appointed a lieutenant in the medical reserve corps of the U. S. Army and assigned to duty Nov. 1, 1918; commissioned in the medical corps of the regular army on July 1, 1920 in the same grade; promoted through the various grades to that of colonel; retired in February 1943 for physical disability; in June 1941 was assigned as commanding officer of the 12th Station Hospital at Camp Forrest, Tenn., and later sent to Camp Callan, Calif.; specialist certified by the American Board of Otolaryngology; member of the Association of the Military Surgeons of the United States; died in the Army Air Forces Hospital March 2, aged 60, of coronary occlusion.

Frank A. Nobiletti ⊕ Forest Hills, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1936; specialist certified by the American Board of Orthopaedic Surgery, Inc.; fellow of the American College of Surgeons; instructor in orthopedics and fractures, and surgeon to the athletic teams at his alma mater; interned and later served a residency in orthopedics at the Bellevue Hospital; served a residency in the department of fractures at the Presbyterian Hospital; a member of the attending orthopedic staffs at the Jamaica Hospital, Mary Immaculate Hospital, Queens General Hospital, Triboro Hospital in Jamaica, Lutheran Hospital, Seton Hospital and the Presbyterian Hospital in New York, where he died April 21, aged 34, of a pulmonary embolism following atypical pneumonia.

Carl Thorburn Harris ⊕ Rochester, N. Y.; Harvard Medical School, Boston, 1916; assistant professor of orthopedic surgery at the University of Rochester School of Medicine and Dentistry; specialist certified by the American Board of Orthopedic Surgery, Inc.; member of the American Orthopedic Association and the American Academy of Orthopaedic Surgeons; interned at the Boston City Hospital; served overseas with Base Hospital number 7 as an orthopedic surgeon during World War I; teaching fellow, surgical pathology, at his alma mater, 1919-1920; chief of the orthopedic service, Genesee Hospital; attending orthopedic surgeon, Highland Hospital; associate visiting surgeon, Rochester General Hospital; died at his home in Honeoye Falls April 17, aged 54, of coronary occlusion.

Solomon J. Appelbaum, Rochester, N. Y.; Johns Hopkins University School of Medicine, Baltimore, 1908; member of the American Medical Association and the Rochester Academy of Medicine; past president of the Medical Society of the County of Monroe and the Rochester Pathological Society; served as director of the Monroe County Tuberculosis and Health Association and the city welfare medical bureau; consultant in medicine at the University of Rochester School of Medicine and Dentistry; on the staffs of the Strong Memorial, Rochester General, Park Avenue, Monroe County and the Rochester State hospitals; past president of the Jewish Social Service Bureau; died in Miami Beach, Fla., April 10, aged 63, of coronary thrombosis.

Thomas Dempsey McKinney, Nashville, Tenn.; Vanderbilt University School of Medicine, Nashville, 1913; since 1936 associate professor of clinical surgery at his alma mater and since 1939 clinical professor of neurosurgery at the Meharry Medical College; at one time president of the Middle Tennessee Medical Society; served seventeen months overseas with the Vanderbilt Medical Unit during World War I, attaining the rank of captain; on the staffs of the Vanderbilt University Hospital, Protestant Hospital, Nashville General Hospital and St. Thomas Hospital, where he died April 12, aged 57, of arteriosclerotic heart disease.

Emil Frederick Baur, Milwaukee; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1900; formerly on the faculty as associate clinical professor of laryngology, rhinology and otology at the Marquette University School of Medicine; served during World War I; on the consulting staff, eye, ear, nose and throat department, Mount Sinai Hospital, where he died April 4, aged 65, of cerebral thrombosis.

Joseph Selic Bendetson ⊕ Brooklyn; University and Bellevue Hospital Medical College, New York, 1920; on the staff of the Jewish Hospital; died March 6, aged 53, of coronary thrombosis.

Frederick O. Blattner, St. Louis; American Medical College, St. Louis, 1901; died in the Desloge Hospital March 12, aged 71, of heart disease.

James Alfred Boyer, Carmi, Ill.; Barnes Medical College, St. Louis, 1899; served during World War I; for twenty years coroner of White County; for many years medical examiner for the Prudential Life Insurance Company; served on the staff of the Veterans Administration Facility in Dayton, Ohio; died March 22, aged 72, of coronary thrombosis.

Mackall R. Bruin ⊕ Los Angeles; University of Maryland School of Medicine, Baltimore, 1895; served as chief consultant in surgery and later as honorary chief consultant at the Methodist Hospital; died March 10, aged 77, of chronic myocarditis and pernicious anemia.

William Herbert Carrigan ⊕ Summerton, S. C.; Medical College of the State of South Carolina, Charleston, 1911; served on the staff of the Roper Hospital in Charleston; member of the county draft board; died in April, aged 59, of coronary occlusion.

Marvin A. Cowden, Shannon, Miss.; Memphis (Tenn.) Hospital Medical College, 1904; member of the American Medical Association; member of the board of aldermen; died April 5, aged 65, of coronary thrombosis.

John Benjamin Frank, Lexington, Ky.; Kentucky School of Medicine, Louisville, 1898; veteran of the Spanish-American War and World War I; died in the Veterans Administration Facility April 8, aged 69, of carcinoma of the lung.

Jeremiah Augustine Greene, Cambridge, Mass.; Harvard Medical School, Boston, 1913; member of the American Medical Association; medical examiner of Middlesex County; on the staff of the Cambridge Hospital; vice president of the University Trust Company and North Cambridge Cooperative Bank; died April 5, aged 59, of angina pectoris.

George C. Grimes, Aspen Hill, Tenn.; University of Tennessee Medical Department, Nashville, 1901; member of the American Medical Association; past president of the Giles County Medical Society; died April 6, aged 79, of heart disease.

John Peter Guilfoyle, Evansville, Wis.; Northwestern University Medical School, Chicago, 1904; member of the American Medical Association; examining physician for the Rock County Selective Service Board number 2; a member of the American Association of Railway Surgeons, serving as local physician for the Chicago and Northwestern System; died in a hospital at Madison, April 13, aged 62, of cerebral hemorrhage, heart disease and tumor of the kidney.

Mathias Grove-Hagen ⊕ Richmond, Va.; Medical College of Virginia, Richmond, 1910; served during World War I; formerly instructor in medicine at his alma mater; member of the Richmond Academy of Medicine; served as physician to St. Joseph's Orphanage for many years; died April 2, aged 65, of hypertensive cardiovascular disease.

John Dunlop Hamill, Brooklyn; Cornell University Medical College, New York, 1901; formerly on the staff of the Misericordia Hospital, New York, where he died April 14, aged 66, of cirrhosis of the liver.

Milton Bruce Hansen ⊕ Moline, Ill.; the School of Medicine of the Division of the Biological Sciences, University of Chicago, 1936; secretary of the Rock Island County Medical Society; past president of the staff of Moline Public Hospital, where he died April 15, aged 40, of cerebral hemorrhage.

Samuel Hirschberg, Newark, N. J.; University and Bellevue Hospital Medical College, New York, 1905; died in April, aged 60, of coronary occlusion.

Samuel Edward Hughes ⊕ Danville, Va.; College of Physicians and Surgeons, Baltimore, 1891; served as vice president of the Society of Chest Physicians of Virginia; resigned in 1940 as medical director of the Hilltop Sanatorium, of which he had been the co-founder; served several terms on the city council; president of the Piedmont Hardware Company; died April 9, aged 80, of myocarditis.

Louis Cornelius Jurgens, Midland Park, N. J.; the Hahnemann Medical College and Hospital, Chicago, 1901; died April 12, aged 75, of carcinoma of the pancreas.

Chad Johnson Kelso, Orlando, Fla.; University of Louisville School of Medicine, 1940; formerly on the staff of the H. F. Long Hospital in Stateville, N. C.; served a residency at the Central Prison Hospital in Raleigh, N. C.; interned at the St. Elizabeth Hospital in LaFayette, Ind., and the Orange General Hospital, where he died April 1, aged 30, of coronary occlusion.

William C. King ⊕ Helena, Ark.; Memphis (Tenn.) Hospital Medical College, 1901; member of the staff of Helena Hospital; died March 27, aged 68.

Junius P. Kinsey, Pinetta, Fla.; St. Louis College of Physicians and Surgeons, 1901; died in the Little-Griffin Hospital, Valdosta, Ga., April 1, aged 72, of brain injury and fracture of the skull sustained in an automobile accident.

Pearl Elizabeth Koch, San Francisco; Washington University School of Medicine, St. Louis, 1938; member of the American Medical Association; served on the staff of the Children's Hospital, where she died April 7, aged 37.

William L. Lancaster, Trenton, Fla.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1908; died April 8, aged 66, of heart disease.

Walter Harrison Loomis, Willoughby, Ohio; Cleveland Homeopathic Medical College, 1904; veteran of the Spanish-American War; died in the Huron Road Hospital, East Cleveland, April 17, aged 71, of congestive heart disease and bronchopneumonia.

Hugh Robert Miller, Lamont, Miss.; University of Tennessee Medical Department, Nashville, 1891; served as a captain in the medical corps of the U. S. Army during World War I; died in the King's Daughters' Hospital at Greenville, April 19, aged 73, following an operation for acute pancreatitis and gallbladder infection.

Robert Fisher Monteith ⊕ Redwood City, Calif.; Rush Medical College, Chicago, 1930; past president of the San Mateo County Medical Society; member of the San Mateo County Sanity Commission; operated the Monteith Clinic since 1941; after serving an internship at the Southern Pacific General Hospital in San Francisco became a resident physician at the Mills Memorial Hospital in San Mateo, where he was later a member of the regular staff and where he died April 10, aged 42, of leukemia.

Harold William Pankow, Wauwatosa, Wis.; Marquette University School of Medicine, Milwaukee, 1938; member of the American Medical Association; found dead in bed April 4, aged 31, of chronic endocarditis and myocarditis.

Harry Parsons, Chicago; the Hahnemann Medical College and Hospital, Chicago, 1880; died April 27, aged 86.

Louis Petruska, Philadelphia; Medico-Chirurgical College of Philadelphia, 1903; member of the American Medical Association; died April 5, aged 73, of carcinoma of the stomach.

Robert McNair Purdie ⊕ Houston, Texas; Northwestern University Medical School, Chicago, 1923; fellow of the American College of Physicians; on the staffs of St. Joseph's Infirmary and the Hermann and Memorial hospitals; died April 9, aged 46, of subarachnoid hemorrhage.

Ida B. Putnam, Chicago; Hering Medical College, Chicago, 1897; died April 11, aged 80, of chronic myocarditis.

John Bruce Ramsey, Forest, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1891; member of the American Medical Association; died in the Nan Travis Hospital, Jacksonville, February 12, aged 78, of meningitis, typhus and bronchitis.

Joseph Spangler Rardin ⊕ Portsmouth, Ohio; Starling Medical College, Columbus, 1890; fellow of the American College of Surgeons; president of the Ohio State Medical Association in 1923; medical officer in the U. S. Army during World War I; member of the staff and for many years instructor of nurses at the Portsmouth General Hospital; surgeon for the Norfolk and Western Railway Company; died March 7, aged 82, of coronary occlusion.

James Henry Rawlings, Lynchburg, Va.; University of Virginia Department of Medicine, Charlottesville, 1898; member of the American Medical Association; on the staffs of the Baptist Hospital and the Memorial Hospital, where he died April 3, aged 74, of cerebral hemorrhage.

Erich Theodor Richter ⊕ Spokane, Wash.; Julius-Maximilians-Universität Medizinische Fakultät, Würzburg, Bavaria, Germany, 1890; past president of the Spokane County Medical Society; died March 12, aged 78, of congestive heart disease and mitral insufficiency.

Charles Alton Rutherford, Seattle; McGill University Faculty of Medicine, Montreal, Que., Canada, 1901; member of the American Medical Association; died March 20, aged 69, of carcinoma.

William John Ryan ⊕ Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1911; member of the founders group of the American Board of Surgery; fellow of the American College of Surgeons and the Philadelphia College of Physicians; on the courtesy staffs of the Germantown and Chestnut Hill hospitals; on the staffs of St. Vincent's Hospital for Women and Children, St. Agnes Hospital and St. Mary's Hospital, where he died April 19, aged 58, of popliteal and mesenteric thrombosis.

Albert F. E. Schierbaum, Mount Angel, Ore.; Washington University School of Medicine, St. Louis, 1894; on the staff of the Silverton Hospital, Silverton; died March 28, aged 72, of chronic myocarditis.

George S. Self, Paragould, Ark. (licensed in Arkansas in 1903); formerly county judge; on the staff of the Dickson Memorial Sanitarium; died March 18, aged 68, of heart disease.

John Francis Sheedy ⊕ Lawrence, Mass.; Baltimore University School of Medicine, 1898; died April 2, aged 73, of coronary thrombosis.

Lillian Shields ⊕ Piedmont, Calif.; Cooper Medical College, San Francisco, 1902; died March 22, aged 71, of carcinoma.

Richard Oliver Simmons ⊕ Alexandria, La.; Louisville (Ky.) Medical College, 1892; president of the Louisiana State Medical Society in 1912; past president of the Rapides Parish Medical Society; member of the Southeastern Surgical Congress; fellow of the American College of Surgeons; for many years health officer of Rapides Parish; on the staff of the Baptist Hospital, where he died April 10, aged 76, of heart disease.

Charles Edward Simpson, Cedar Rapids, Iowa; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1898; died March 14, aged 71, of uremia and nephritis.

Vergil Rex Sink, Winston-Salem, N. C.; University of Pennsylvania School of Medicine, Philadelphia, 1928; member of the American Medical Association and the American Academy of Ophthalmology and Otolaryngology; specialist certified by the American Board of Otolaryngology; on the staffs of the North Carolina Baptist Hospital and the City Memorial Hospital, where he died March 28, aged 45, of coronary thrombosis.

Thomas Martin Smith, Jeffersonville, Ind.; Hospital College of Medicine, Louisville, Ky., 1906; served during World War I; died March 29, aged 62, of cerebral hemorrhage and uremia.

Robert Rice Snively, Chicago; University of Illinois College of Medicine, Chicago, 1940; member of the American Medical Association; interned at the Research and Educational Hospitals; served a residency at the St. Francis Hospital in Blue Island, Ill.; on the courtesy staff of Wesley Memorial Hospital, where he died April 19, aged 32, of thrombosis of the inferior and superior vena cava.

Walter C. Sooy, Woodcrest, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1890; formerly police surgeon; died March 30, aged 75, of nephritis, diabetes mellitus and osteomyelitis of the left tibia.

William James Sweeney, Weehawken, N. J.; Albany Medical College, Albany, N. Y., 1911; fellow of the American College of Surgeons; past president of the board of education; attending surgeon, Christ Hospital, Jersey City; member of the courtesy staff of the Holy Name Hospital, Teaneck; for many years a physician for the New York Central Railroad; died April 22, aged 62, of heart disease.

Robert Campbell Tarbell, Columbus, Ohio; Medical College of Ohio, Cincinnati, 1897; past president of the Columbus Academy of Medicine; died in the Grant Hospital, Columbus, April 15, aged 74, of myocarditis.

William Bibb Thornhill, Lynchburg, Va., Hospital College of Medicine, Louisville, Ky., 1886; member of the American Medical Association; served on the city board of health for many years; on the staffs of the Virginia Baptist and Lynchburg General hospitals; died April 3, aged 82, of embolism.

Speare Owen Turner, Jackson, La.; University of the South Medical Department, Sewanee, Tenn., 1909; Memphis (Tenn.) Hospital Medical College, 1910; served during World War I; major, medical reserve corps, U. S. Army, not on active duty; formerly Beauregard parish coroner and health officer; for many years a member of the staff of the East Louisiana State Hospital; died April 13, aged 60, of arteriosclerotic heart disease.

Joseph Atwood Van Arsdall, Nicholasville, Ky.; University of Louisville Medical Department, Louisville, 1891; member of the American Medical Association; president of the high school board and vice president of the Farmers Bank; died April 14, aged 76, of carcinoma of the prostate with metastases.

Ernest Davis Vanderburgh, West Fulton, N. Y.; University of the City of New York Medical Department, New York, 1894; for many years a medical missionary in China; formerly affiliated with the Asheville (N. C.) Farm School; died in Gilbertsville April 21, aged 74, of subarachnoid hemorrhage.

William Claybourne White ⊕ Louisville, Ky.; Atlanta College of Physicians and Surgeons, Atlanta, Ga., 1905; fellow of the American College of Surgeons; served in the medical corps of the U. S. Army during World War I; died in St. Joseph Infirmary April 6, aged 73, of coronary thrombosis.

Thomas Alfred Whitfield ⊕ Nashville, Tenn.; University of Nashville Medical Department, 1908; a first lieutenant in the medical corps of the U. S. Army during World War I; member, Selective Service Board, during World War II; captain in the Civil Air Patrol; formerly on the staffs of St. Thomas, Protestant and Nashville General hospitals; member of the Middle Tennessee Medical Association, Southern Medical Association and the Nashville Academy of Medicine; died April 8, aged 58, of coronary occlusion.

Hugh Williams ⊕ Boston; Harvard Medical School, Boston, 1898; member of the American Surgical Association and the New England Surgical Society; fellow of the American College of Surgeons; consulting surgeon, Massachusetts General Hospital; served for many years on the staffs of hospitals in Natick, Gardner and Peabody, Mass., and Brattleboro, Vt.; died February 22, aged 72, of terminal bronchopneumonia.

DIED WHILE IN MILITARY SERVICE

Roger Sherman Downs ⊕ *Lieutenant (MC),* U. S. Navy, Litchfield, Conn.; Harvard Medical School, Boston, 1936; served an internship and residency at the Strong Memorial and Rochester Municipal Hospitals in Rochester, N. Y.; served a residency at the Peter Bent Brigham Hospital in Boston; began active duty as a lieutenant (jg) in the medical corps of the U. S. Navy in October 1942; later promoted to lieutenant; for the past two years has been on duty in North Africa, Sicily and Italy; recently assigned to duty with the Third Naval District Headquarters, New York; found dead in bed in New York February 6, aged 34, of arteriosclerosis of the coronary arteries and shock.

Robert Charles Gavin, Fond du Lac, Wis.; University of Wisconsin Medical School, Madison, 1943; interned at the Cincinnati General Hospital; entered the medical corps of the U. S. Naval Reserve as a lieutenant (jg) on March 20, 1943; began active duty on Jan. 10, 1944; medical officer aboard the U. S. S. *Monaghan,* a 1,300 ton destroyer assigned to Admiral Halsey's Third Fleet; drowned in the Asiatic area Dec. 18, 1944, aged 26, when the *Monaghan* and two other ships capsized in a typhoon that struck the carrier task force to which the three ships were assigned.

James Donal O'Connor, Peoria, Ill.; St. Louis University School of Medicine, 1930; member of the American Medical Association; interned at De Paul, Missouri Pacific and Barnard Free Skin and Cancer hospitals, all in St. Louis; commissioned a captain in the medical corps, Army of the United States, Aug. 31, 1942; began active duty on Oct. 2, 1942; assistant chief of medical service at the Air Force Base Hospital at Eglin Field, Fla.; died in Coral Gables, Fla., February 24, aged 39, of increased intracranial pressure caused by brain tumor of the right temporal lobe.

Correspondence

THE WAGNER-MURRAY-DINGELL BILL

To the Editor:—On Thursday, May 24, I introduced with Senator Murray a bill, S. 1050, entitled "The Social Security Amendments of 1945." The bill provides for "the national security, health and public welfare." Representative Dingell of Michigan introduced a companion bill (H. R. 3293) in the House at the same time.

I particularly invite your earnest study of the provisions of the bill relating to health. There is absolutely no intention on the part of the authors to "socialize" medicine, nor does the bill do so. We are opposed to socialized medicine or to state medicine. The health insurance provisions of the bill are intended simply to provide a method of paying medical costs in advance and in small convenient amounts.

During the formulation of this bill, we have benefited greatly from the constructive advice and suggestions of practicing physicians, and of physicians in clinical and teaching positions. Their constructive suggestions have resulted in changes in the bill which we presented in the last Congress. Undoubtedly other changes will be made before this bill is enacted into law. We wish to have it known that we invite constructive suggestions from the medical profession.

In addition, members of the medical profession will be given *full* opportunity to voice their opinions in open hearings when the bill is considered in committee.

I hope that you will print this letter in THE JOURNAL and that you will join me in urging the medical profession to undertake an earnest study of the actual provisions of the bill. In this way you can help immeasurably in avoiding misunderstanding and misinterpretation of the legislation and in stimulating physicians and medical and hospital organizations to come forward with constructive suggestions and advice.

ROBERT F. WAGNER,
United States Senate,
Washington, D. C.

THE DISCOVERY OF ANTIBIOTICS IN GENERAL AND PENICILLIN IN PARTICULAR

To the Editor:—Two main stages characterize the development of penicillin studies: (1) the discovery of the antagonism between certain micro-organisms including molds and (2) the sequence of attempts to concentrate and isolate antibiotics. During the first stage, observations were accumulated on the bacteriostatic, bactericidal and lytic effects of various molds. The discovery of the antibiotic action of molds on bacteria was by no means necessarily linked to observations on penicillin alone. True, Fleming showed that within the group of Penicillium the *notatum strain singularizes itself* with regard to the secretion of penicillin. However, Fleming's casual observation in 1929, which happened to deal with the particular strain of Penicillium notatum, did not represent the beginning of the aforementioned period. Several years before him, in 1924 and 1925, Gratia described at length very closely related phenomena regarding the lytic effect determined by the action of molds on bacteria. He was handling at the time various species and according to his indications it may well be that Penicillium notatum was included *in some of his* experiments. In 1921 Lieske described similar findings, as recalled by Gratia himself.

What is entirely *personal to Fleming* is his early observation in 1922 on what he called lysozyme, a principle which he considers an enzyme and which he *identified in* tears. It was described as having a bactericidal effect on saprophytes of the air and it apparently was *considered to be* an endogenous property of lacrimal secretions. Lysozyme has also been identified in egg white by Fleming.

Only when the second stage of research on antibiotics was given a start in 1932, when Raistrick began to produce penicillin and when Florey and Chain followed in 1936, did the science of antibiotics develop considerably. This period, which is characterized by the attempts to isolate and concentrate antibiotics, is a result of four years of painstaking work accomplished by Florey, Chain and others. With this purpose in mind, the choice of penicillin as the most suitable antibiotic to work with was relevant. The outstanding merit of these workers was to have foreseen the possible use in the future of antibiotics as new therapeutic agents against certain infections, to have selected Penicillium notatum as the most appropriate material to start with and finally to have succeeded in extracting penicillin.

The main object of this note is to put into proper perspective the work of A. Gratia in the sequence of observations of antibiotic action of molds on pathogenic bacteria.

Synopsis of Observations Enumerated by Fleming as Compared to Gratia's

Fleming	Gratia
1. Staphylococcus colonies became transparent and were obviously undergoing lysis under the action of a contaminating mold (1929)	1. Remarkable clarification of a staphylococcic medium by a "small white fungus bearing the characteristics of streptothrix" (1924)
2. The fungus filtrates proved to be strongly inhibitory against pyogenic cocci and diphtheric bacilli but were inefficient where some other bacteria were concerned	2. (*a*) The active principle separated from the fungus by filtration *is capable* of dissolving a new emulsion of staphylococci (1924) (*b*) These antibiotics obtained *from mold* cultures produce the lysis of several germs, including gonococci (1925 *)
3. Penicillin may be an effective antiseptic for applications to, or injection into, areas infected with *penicillin sensitive* microbes	3. (*a*) Such antibiotics can be injected parenterally into animals and into men in large quantities without ill effects † (*b*) Patients suffering from the staphylococcic infections have been cured with such antibiotics

* A. Gratia and S. Dath (1925): "In an ampule of *contaminated* enterovaccine we have found a variety of streptothrix very active against the dysenteric typhoidal and paratyphoidal species. From a culture containing contaminated carbuncular bacillus, completely *clarified*, we extracted a variety of Penicillium glaucum which dissolves carbuncular bacterium."

† 1931, in collaboration with Alexander and Jaumain.

Gratia and his associates as early as 1924 stipulate in the most explicit way that they had prepared mycolysates bearing antibacterial potency. This was five years before Fleming's work.

Clearly, as shown in the accompanying synopsis comparing the observations of Fleming and of Gratia, Fleming's observations are much in agreement with Gratia's earlier discoveries. This is especially true when the latter mentions having used the mycelium steep liquor after having crushed the hyphae. The facts cited by the two investigators are almost identical, but the species of molds they used may have been different. With regard to therapeutic applications, however, Fleming and Gratia had different ideas in mind. The former mentioned the therapeutic value of the antibacterial effect of the mold itself, as a prognostication, whereas Gratia's line of thought was polarized toward vaccination. The injecting material used by Gratia was in every instance a mixture of mother liquor from the fungi, i. e. the lytic agent and disintegrated bacteria. He was primarily concerned with the antigenic substances contained in his mixtures, which derived from the dissolved bacteria but not with the bactericidal principle of his mixtures which derived from this mold.

The facts of outstanding and also of practical value on which all the emphasis should be laid belong to the Oxford scientists, who under the leadership of Chain and Florey have found:

1. A method for increasing the yield of penicillin preparations and greater reliability in measuring their antibacterial power (1940).

2. The original method for large scale production (1941).

3. The proof that purified penicillin preparations lack toxicity even in very high doses.

4. Outstanding clinical results obtained in a great many infectious diseases and in some cases in which sulfonamide compounds have failed.

MEDICOLEGAL ABSTRACTS

Medical Practice Acts: Failure to Keep Records of Narcotics Dispensed as Crime Involving Moral Turpitude.—Brainard, who was licensed to practice medicine in California, was charged with violating section 11225 of the Health and Safety Code, California, Statutes 1939, page 761, in failing to keep records of narcotics dispensed. He pleaded guilty and was given a suspended sentence of one day. Later proceedings to revoke his license were instituted before the board of medical examiners, charging that he was guilty of unprofessional conduct and alleging that the conviction just referred to constituted a conviction for a crime involving moral turpitude, which under the applicable California statutes is unprofessional conduct. After a hearing the board revoked his license and he filed with the superior court, Los Angeles County, a petition for a writ of mandate to require the board to restore his license. From a judgment in favor of the board, he appealed to the district court of appeal, second district, division 2, California.

Brainard contended that the evidence adduced before the board was insufficient to justify the revocation of his license. He argued that the offense of which he was convicted was not a crime involving moral turpitude and he pointed to the fact that after that conviction on his plea of guilty he was given a suspended sentence of one day. The board of medical examiners, said the appellate court, has authority to revoke the certificate of a physician who is found guilty of unprofessional conduct and it is expressly provided by statute that conviction of any offense involving moral turpitude constitutes unprofessional conduct. Business and Professions Code, sec. 2383. The section of the Health and Safety Code, for the violation of which Brainard was sentenced, makes it a public offense for any one to administer or dispense narcotics without making a record of the transaction, which record is open to inspection by specified state officers. True, that offense is not a felony; but the section of the Business and Professions Code just referred to does not require the offense of which the holder of a license is convicted to be a felony. It is merely required that the conviction be "of any offense involving moral turpitude." Whether or not the offense committed did in fact involve moral turpitude depends on all of the surrounding circumstances. The board of medical examiners was not limited by the sentence imposed by the court by which Brainard was convicted of the offense. The board was justified in hearing evidence concerning all of the circumstances surrounding the offense for the purpose of determining if indeed moral turpitude was involved, and the same rule was applicable when Brainard filed his application for a writ of mandate in the lower court. The record before this court, continued the court, contains ample evidence to sustain the board's finding that Brainard was guilty of an offense involving moral turpitude. An inspector for the Division of Narcotic Enforcement testified that on a certain day he and another inspector gave marked money to a narcotic addict, who then entered Brainard's office and returned with narcotics. According to the testimony, the same procedure was followed two days later and the marked money was recovered from Brainard. When confronted by the inspectors Brainard asserted that although he had read the state narcotic act he did not know that he had to keep records and that the addict in question was a sick man. An examination of Brainard's records and of his stock disclosed a shortage in his supply of narcotics. The markings on the arm of the addict and his general physical appearance indicated quite clearly that he was a narcotic addict. The court accordingly concluded that the evidence referred to was sufficient to sustain the board's finding that Brainard was guilty of an offense involving moral turpitude.

Brainard next contended that he was deprived of his license without due process of law, basing his assertion on the fact that he was charged in the complaint filed with the board of medical examiners with the commission of a misdemeanor. But, answered the court, in the charge before the board it was set forth that Brainard had been convicted of a crime involving moral turpitude, and although it was specifically set forth that he was guilty of violating section 11225 of the Health and Safety Code, the language of the charge was such that Brainard was notified that he would be called on to meet the accusation that the circumstances surrounding the commission of the offense involved moral turpitude. He was given an opportunity to meet this charge at the hearing which was accorded him. It is not claimed that a charge of unprofessional conduct may not be based on the furnishing of narcotics to an addict.

The order of the board revoking his license to practice medicine, in effect, was affirmed.—*Brainard v. Board of Medical Examiners of California, 157 P. (2d) 7 (Calif., 1945).*

BOARDS OF MEDICAL EXAMINERS

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in The Journal, June 2, page 385.

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: Parts I and II, July 16-18. Part III. Various centers, June. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th St., Philadelphia.

EXAMINING BOARDS IN SPECIALTIES

American Board of Internal Medicine: *Oral.* Chicago, June 27-29, San Francisco, Oct. 15-17. *Written.* Various centers, Oct. 15. Final date for filing application is Aug. 1. *Candidates in the armed forces may take the examination at their station with the permission of their medical commanding officer.* Asst. Sec., Dr. W. A. Werrell, 1301 University Ave., Madison 5, Wis.

American Board of Obstetrics & Gynecology: *Part II. Oral.* Atlantic City, June 13-19. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh 6.

American Board of Ophthalmology: New York, June 13-16; Chicago, Oct. 4-6; *and Los Angeles, January.* Sec., Dr. S. Judd Beach, 56 Ivie Rd., Cape Cottage, Me.

American Board of Orthopaedic Surgery: *Part I. Oral and Written.* New Orleans, Sept. 28-29, Philadelphia, Oct. 5-6, Chicago, Oct. 12-13 and San Francisco, Oct. 19-20. *Final date for filing application is August 1.* Sec., Dr. G. A. Caldwell, 3503 Prytania St., New Orleans 15.

American Board of Otolaryngology: Chicago, Oct. 3-6. Sec., Dr. Dean M. Lierle, University Hospital, Iowa City, Ia.

American Board of Pediatrics: *Written. Locally, Oct. 19. Oral.* New York, Dec. 7-8. Sec., Dr. C. A. Aldrich, 115½ First Ave., S.W., Rochester, Minn.

American Board of Radiology: *Oral.* Fall, 1945. Final date for filing application is Aug. 1. Sec., Dr. B. R. Kirklin, Mayo Clinic, Rochester, Minn.

American Board of Surgery: *Written.* Various centers, October 24. Final date for filing application is Aug. 1. Sec., J. S. Rodman, 225 S. 15th St., Philadelphia 2.

American Board of Urology: *Written.* Chicago, Dec. 9. *Oral.* Chicago, Feb. 19-22. Sec., Dr. Gilbert J. Thomas, 1409 Willow St., Minneapolis 4.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

*Apparent Arrest of Staphylococcal Endocarditis. W. J. MacNeal, C. A. Poindexter and F. N. Marty.—p. 403.

Effect of Coronary Artery Ligation.—Govier estimated cocarboxylase and coenzyme I in normal and ischemic heart muscle, with and without the administration of nicotinamide, riboflavin and succinate. He found that coenzyme I is destroyed to the extent of 70 to 83 per cent of normal in cardiac muscle rendered ischemic by coronary artery ligation. Nicotinamide, nicotinamide and riboflavin, and succinate, when administered intravenously before coronary ligation, protect to a great extent against such breakdown of coenzyme I. Nicotinamide and succinate are only fairly efficient in remedying this destruction when injected after the occlusion has been established. No significant change in tissue cocarboxylase occurs after coronary ligation.

Apparent Arrest of Staphylococcic Endocarditis.—A man aged 36 with rheumatic heart disease, aortic and mitral insufficiency, Staphylococcus aureus bacteremia and bacterial endocarditis was treated with sulfadiazine. The treatment had to be discontinued because of renal irritation. Later he was treated with staphylococcus bacteriophage and thiobismol and after that with penicillin. Blood cultures, which had been consistently positive, became negative. MacNeal and his associates recognize that a diagnosis of staphylococcic mitral endocarditis may be disputed in the absence of an anatomic and cultural study of the cardiac valves themselves but believe that this patient actually suffered from bacterial mitral endocarditis caused by infection with Staphylococcus aureus and that the disease is now in a stage of arrest which may be permanent.

Incidence and Transmission of Filaria.—According to Causey and his associates, filariasis has long been known to be endemic in Belem (state of Pará), Brazil. Studies on random samples of the human and mosquito population of Belem were made from November 1942 to December 1943 to investigate the current incidence and distribution of filariasis and the prevalence of infected mosquitoes. Both by the morphology of the embryo and also by the periodicity in the human host the filaria was recognized as Wuchereria bancrofti. Fourteen parasitized persons were hospitalized to provide material for a study of periodicity. Blood samples of 20 cubic millimeters taken at three hour intervals from 8 patients over a twenty-four hour period showed nocturnal periodicity of microfilariae. All patients were negative at 3 p. m., 1 was positive at 6 p. m., 5 were positive at 9 p. m., 7 were positive at midnight and all were positive at 3 a. m. At 6 a. m. 7 were positive, at 9 a. m. 6 were positive and by noon only 3 remained positive. Collectors visited houses in various sections of the city, made thick blood films from all persons encountered in each house and recorded all cases of elephantiasis observed. The examination of thick blood films from 5,000 persons revealed that 541 (10.8 per cent) of this sample harbored microfilariae. Elephantiasis was observed in 1.3 per cent of the persons examined. If the cases of elephantiasis not showing microfilariae are included as true cases of filariasis the incidence rate of filariasis for the total sample of 5,000 persons is 12 per cent. An analysis by age groups showed an increasing incidence of microfilariae with age. The youngest person with microfilariae in the blood was a boy aged 2 years and the youngest person with elephantiasis was a boy aged 11 years. The principal vector was found to be Culex fatigans. Among 1,014 dissections, 118 specimens were positive for filaria larvae. Anopheles darlingi and Anopheles aquasalis also were found naturally infected.

Distribution of Poliomyelitis Virus.—Pearson and Rendtorff's first study of the distribution of poliomyelitis virus was concerned with the environment of sporadic cases. Testing stool specimens from almost the entire population of a village where poliomyelitis occurred in an adult, they recovered virus only from the 6 year old son of the patient. Pools of specimens from 127 persons in 39 families were uniformly negative. Of 30 persons associated with a poliomyelitis patient in a small town, virus was recovered only from the stools of a sibling aged 5 years and from 2 playmates aged 7 and 5 years of another family. No virus was detected in the stools of the associates of 2 patients on farms or of 2 patients in a small town. Virus was not recovered from fecal specimens from farm animals or from flies, mosquitoes or the brains and intestines of rats or mice from the environment of these sporadic cases. In the second study stool samples from nearly all the children under 16 years of age were tested for the presence of virus after the occurrence of 2 cases of poliomyelitis in a small town. Members of the families of the patients also were tested. Of 282 persons in 146 families, virus was recovered

from the brother and a group of 3 cousins of 1 patient and from children of 8 other families; 5 of these children were 2 years of age. From the degree of association of those found to harbor the virus, it was concluded that personal association was the principal factor involved in the spread of infection within the community. The third study concerned the distribution of virus in a selected district of Fort Worth during the 1943 epidemic of poliomyelitis Stools from 524 persons were tested for virus by inoculation into monkeys. Six of 8 households, representing 27 familial contacts, were positive for virus, as were 8 of 45 households containing 80 nonfamilial contacts and 2 of 127 households representing 374 noncontacts Virus was harbored by adults in 5 of the 6 positive households of familial contacts Virus was not recovered from specimens of water, sewage, flies, ants, cockroaches or droppings of domestic animals. An agent that produced paralysis in mice and cotton rats was obtained from a pool of brains and intestines from 22 rats from the city dump. No virus was recovered from several batches of mice and rats collected in various other parts of the city.

Burns and Liver Function.—Saltonstall and his associates studied liver function of patients with burns admitted to eleven hospitals in the Philadelphia area. Most of the patients were treated locally with petrolatum gauze and pressure dressings. A combination of the van den Bergh test, the sulfobromophthalein retention, the hippuric acid conjunction test and the cephalin flocculation test gave an index that was fairly well correlated with the results of the van den Bergh test. Of a series of 38 patients studied prior to 1943, 34 were treated with tanning methods. The 47 cases treated in 1943 and have been treated by open methods. The authors found tannic acid impairs liver function following burns In patients treated with petrolatum gauze and pressure dressings the liver function is likewise impaired, but the impairment is usually mild The abandonment of tannic acid in the local treatment of burns has not resulted in a decrease in mortality. It seems unlikely that the increase in liver damage observed when tannic acid is used is of great significance in the mortality among burn patients. Hepatic damage is probably not the primary cause of death in burn toxemia.

Central Nervous System Changes as a Cause of Death in Burns.—Of 6 patients 5 died in sudden respiratory failure when the renal and hepatic damage associated with burn toxemia was decreasing in severity. The sixth patient had two episodes of apnea during the toxemic period but survived to die sixty two days later of a pulmonary embolus The brain in this case showed evidence of damage of the same type but of lesser degree than was seen in the other 5 patients. Gross examination of the brain revealed evidence of increased intracranial pressure with herniation of the cerebellar tonsils through the foramen magnum compressing the medulla. Photomicrographs showed severe interstitial edema and ganglion cell changes, which were most noticeable in the hypothalamus. Walker and Shenkin suggest that the central nervous system changes are an important factor in the sudden deaths occurring in the toxemic phase of burns

Wheal Fluorescence: Method of Evaluating Peripheral Vascular Diseases.—Neller and Schmidt suggest a test which reveals the extent and degree of peripheral vascular insufficiency The patient is placed in a room which can be darkened, and the inner or outer aspect of the entire leg and foot on both sides is prepared by washing with alcohol. A series of superficial scratches are made at 2 inch intervals down the legs in comparable places The lowest scratch mark can be made at the base of the toes on the dorsum of the foot The scratches are made by repeatedly (five to ten times) stroking the skin in the same spot with a hypodermic needle. As soon as the marks are completed, 5 cc. of a 20 per cent sodium fluorescein solution is injected intravenously. The room is darkened, and filtered ultraviolet light is played on the scratched areas. The test can be read within one to two minutes, which is just about the time necessary to darken the room and allow ultraviolet light to reach its peak intensity. The test remains readable for over an hour. The major fact to observe is the level at which the marks cease to be fluorescent. This change is abrupt and easily seen. Results indicate that scratch fluorescence gives reliable factual data regarding the degree and extent of vascular impairment.

Local Penicillin for Pyogenic Dermatoses.—Templeton and his associates found that penicillin, whether used as peritrol lium gauze, as a solution of the crude penicillin or as purified penicillin in ointment bases, is a valuable therapeutic agent in

the local treatment of the pyogenic infections of the skin. They gained the impression that it works well only for superficial diseases solely or largely due to pyogenic infection. When the infection is deep in the skin, as in sycosis vulgaris or erysipelas, surface applications of penicillin are of questionable value.

Treatment of Sinusitis with Penicillin.—Hauser and Work used penicillin in the treatment of 46 cases of sinusitis. Eleven were treated by irrigation of the maxillary antrums with solutions of penicillin, and 35 were treated by intramuscular injection of penicillin alone or in conjunction with radical surgical opening of the sinuses. When penicillin was used in conjunction with adequate surgical treatment of the sinuses, results were far better than before penicillin was available. It is not advisable to abandon surgical procedures, as was proved in 3 cases of intracranial complication of sinus disease in which penicillin was utilized over long periods and in adequate amounts before surgical intervention was attempted. In these cases operation revealed that the penicillin alone had not cured the sinusitis; following adequate surgical treatment, the sinusitis was rapidly cured. The authors at first gave penicillin weeks after operation in an attempt to reduce the amount of exudate in the nose. Noting the rapid cessation of discharge resulting from the use of penicillin, they began to give it immediately after operation. The results were gratifying in that the discharge disappeared rapidly. In the most recent cases they began the administration of penicillin forty-eight hours before operating on the sinuses. The postoperative reactions were minimal, and rapid and uneventful recovery followed. At present every patient who is to have radical surgical treatment for sinusitis receives penicillin intramuscularly every three hours for two days prior to operation, and its administration is continued postoperatively until maximum benefit has been obtained.

Aerosinusitis.—Aerosinusitis is an acute or a chronic inflammation caused by trauma to the mucous membrane of a sinus which occurs during airplane flights. Changes in barometric pressure are the immediate cause of aerosinusitis. Obstructing tissue is the predisposing cause. The rate of change in barometric pressure is of utmost importance. A slow change will give air of different densities opportunity to equalize through even a restricted sinus opening. A rapid change of pressure may force redundant tissue into the openings so quickly and build up differential pressure so rapidly that no aeration is possible. The symptoms occur chiefly on descent. Pain, the predominant symptom, is present only for a short time. The most severe physical effect on the sinuses produced by change in barometric pressure was observed in an aviation cadet who entered the hospital seven days after he had been on a routine flight in the low pressure chamber to 38,000 feet (11,580 meters) for three hours. On descent he experienced a severe pain in the left side of his face. The following day he complained of pain and numbness on the left side of his face. On the second day there was a discharge of blood from the left nostril. After a few days he showed improvement and was dismissed, but he returned because the pain and numbness had become intensified. The left antrum was opened. The Caldwell-Luc procedure was carried out. The periosteum of the canine fossa was bound down by fibrous reaction. The bone was thin and easily removed. When the sinus was opened a bluish membrane bulged out under pressure. Incision of the membrane revealed the cavity filled with many blood clots. It seems justified to assume that the hemorrhage in the submucosa was caused by relative negative pressure which pulled the mucosal layers apart, thus rupturing the blood vessels. This is what happens to the layers of the drum membrane in aero-otitis media with resulting hemorrhage between the layers. It is impossible to say whether or not a candidate with a certain nasal apparatus can fly without difficulty. A large number of candidates have been seen with severe pathologic nasal changes who have had no symptoms on repeated flights. Many with repeated difficulty showed much less pathologic change on examination than nonsymptomatic candidates. The treatment attempts to equalize the differential pressure.

Venous Thrombosis and Pulmonary Embolism.—According to Linton, bilateral femoral vein interruption is a safe procedure which will prevent massive fatal pulmonary embolism in patients with deep venous thrombosis of the lower extremities. The operation should be carried out on patients who have developed nonfatal pulmonary embolism, even though no positive signs of venous thrombosis in the legs can be detected, and on any patient who develops deep phlebitis of the lower extremities. Interruption of the femoral vein should be done on both sides even if the venous thrombosis is diagnosed on only one side, because patients with unilateral femoral vein interruption have died from a massive pulmonary embolus which arose from the unligated side. Thrombectomy by aspiration in cases of femoral iliac thrombosis has been demonstrated to be a safe procedure. It should be done as early as possible after the thrombosis has been diagnosed. It reduces the pain and

swelling in the leg and hastens the recovery, in addition to preventing massive fatal pulmonary embolism. No deaths have occurred in 202 cases as the result of femoral vein interruption. The morbidity of thromboembolic disease is tremendously reduced by this operation. Interruption of the inferior vena cava distal to the renal veins is the operation of choice in cases of long standing thrombophlebitis with pulmonary embolism.

Intravenous Clotting.—Simon points out that the syndrome formerly referred to as thrombophlebitis is now differentiated into thrombophlebitis and phlebothrombosis. Clotting in thrombophlebitis is the result of injury to the vascular endothelium from mechanical trauma, bacterial invasion or chemical injury, whereas in phlebothrombosis the thrombus is a result of venous stasis and alterations in the clotting tendency of the blood. There is also difference in the prognosis: in thrombophlebitis the clot is firmly adherent to the vein wall and is not likely to become detached as an embolus, while in phlebothrombosis the clot is loosely attached to the vessel wall and is likely to cause embolism. The clinical manifestations of the two types of clotting are quite different. In thrombophlebitis there is usually fever. The patient also has pain and swelling in the region of the involved vein. Patients with phlebothrombosis may have no symptoms at all. They frequently have a feeling of impending disaster but no pain, no fever and usually no swelling. It is in this type of patient that on the eighth to the tenth day postoperatively, when preparing to get out of bed or while straining at stool, the dramatic syndrome of pulmonary embolism occurs. Phlebothrombosis should be suspected in a patient who shows unusually rapid pulse and tenderness of the feet or calves. When the diagnosis of phlebothrombosis is made, aspiration of the thrombus and division of the vein should be done, while thrombophlebitis responds dramatically to sympathetic ganglion block.

Thymus Tissue Transplanted to Wound.—Because it has been suggested that the small lymphocyte may have a function in the formation of fibrocytes and collagen fibers, thymus tissue, in which this cell is abundant, was taken from rats 3 to 6 weeks old and applied to the surface of open wounds made on adult rats of the same strain. A stratified squamous epithelium was developed on the surface of skin wounds. This epithelium was derived from the thymus reticulum cells. Such a change in the thymus tissue is not surprising when other evidence of the potentialities of the thymus reticular cell is reviewed.

Failure of Homogenous Nerve Grafts.—Spurling and his associates analyze the histologic changes in a number of whole fresh homogenous nerve grafts placed in peripheral nerve defects in man subsequent to extensive gunshot wounds of the upper and lower extremities. There was no clinical evidence of nerve regeneration after an appropriate time interval had elapsed following transplantation of the neural tissue. When failure was manifest, the engrafted segment, including adjacent proximal and distal nerve areas, was excised and was replaced with a

nerve graft of a different character. Clinical records of 2 patients illustrate the salient results of this study. The proximal and distal nerve ends must be prepared through normal appearing tissue. This basic principle applies to the scarred, often edematous, nerve trunk, which may lie just central to the neuroma, and to the distal nerve end, which may be extensively fibrosed. Tantalum wire, 0.003 inch in diameter, was used as an interrupted suture, and every effort was made to keep it within the epineurium. The application of tantalum foil cuffs appears highly significant. The nerve ends and segments of grafts protected by the foils were relatively normal in appearance where the unprotected segments were ensheathed by constricting adhesions. In 1 case in which foil was placed around the proximal junction and a protein film about the distal anastomosis, the beneficial effect of the former is well illustrated. The entire graft may need mechanical protection from the adverse influence of the graft bed tissues. One of the main points of difference between successful animal homografts and human failures may lie in the girth of the engrafted tissue. Blood vessels, fat, epineurium and a considerable amount of interfascicular tissue may be removed from the neural tissue of a large human nerve trunk. No attention was paid to the blood groups, and it was found that a patient receiving a graft from within the same blood group fared no better than an O recipient obtaining a graft from an A donor. In all of the proximal stumps and grafts studied, areas exhibiting good nerve growth were always well vascularized; but it seemed that a rich blood supply to the tubules within a graft fascicle did not guarantee their neuromotization. The actual bridging of the gap between regenerating fibers and the distal nerve may be achieved by the summation of a multitude of technical and biologic refinements.

Combined Use of Fibrin Film and Clot in Union of Nerves.—Singer describes a method of uniting nerve stump without the use of thread sutures. The technic, designated as the fibrin adhesive method, involves the use of a thin smooth film of fibrin prepared from products of fractionation of human blood plasma. The film is impregnated with thrombin, surfaced with fibrinogen and then applied to the apposed nerve stumps by one of several methods. The fibrinogen as it clots binds the film to the surface of the nerve and thus serves to transmit the stress of retraction of the stumps to the film. In addition to maintaining apposition of the stumps, the film serves as an envelop enclosing the nerve stumps and nerve wound in a continuous channel. The fibrin adhesive method of nerve splicing has the advantages of simplicity of application and of introducing no extraneous materials or obstacles to growth into the nerve trunks themselves or between the stumps. The film is transparent and consequently allows for continued observation of the nerve stumps throughout the operation.

Denonvilliers' Fascia.—Tobin and Benjamin describe studies on human embryos and on specimens from adults. The tissue known as Denonvilliers' fascia was observed to be derived embryologically from two sources of connective tissue (mesenchyme): (1) a layer surrounding the developing prostate and seminal vesicles and another layer around the rectum and (2) connective tissue (mesenchyme) adjacent to the mesothelium of the pelvic cul-de-sac of peritoneum. The authors suggest that the fascia around the rectal musculature be designated the posterior layer and that the fibrous membrane which is derived from the pelvic cul-de-sac of peritoneum be designated the anterior layer of Denonvilliers' fascia. In the perineal approach to the prostate, three potential fascial spaces could be developed between the rectum and prostate: (1) between the rectal musculature and rectal fascia (posterior layer of Denonvilliers' fascia), (2) between the rectal fascia and anterior layer of Denonvilliers' fascia and (3) between the anterior layer of Denonvilliers' fascia and the fibromuscular covering of the prostate and seminal vesicles. Since the anterior layer of Denonvilliers' fascia and the fibromuscular covering of the prostate are whitish in appearance and close together or adherent, either or both of these layers may constitute the glistening layer encountered in the perineal exposure of the prostate. If the fibromuscular covering of the prostate should be perforated by cancer or abscess, the fibrous membrane (anterior layer of Denonvilliers' fascia) might prevent direct spread of the malignant growth posteriorly to the rectum and might limit the spread of extravasated pus or urine. In the specimens studied by the authors the fascial spaces between the rectum, prostate and seminal vesicles were separated more readily if they were not compressed by instrumentation through the urethram or rectum in the first stages of the perineal approach.

Human Transmission of Infective Hepatitis by Oral Route.—Infective hepatitis can be transmitted to man by a number of routes. The etiologic agent (probably a virus) is in the blood stream before the onset of and during jaundice; it is present in feces during acute stages of the disease and probably also in nasal washings. Newer (unpublished) experiments by one of the authors establish that the agent of infective hepatitis can be carried in serial passage in man (two passages), thus indicating the infectious nature of the disease. Like the agent of serum jaundice (with which it may be identical) it is filtrable and heat stable, withstanding 56 C. for half an hour. More recent observations indicate that in cases of infective hepatitis the virus or icterogenic agent is in the feces and that the disease can be produced in man by feeding such material in capsules or by spraying it into the nasal and pharyngeal passages. Similarly the disease can be produced by feeding serum from cases of infective hepatitis. In the feeding cases the incubation periods have on the average been about twenty-eight days, being shorter than the incubation periods of typical serum jaundice. There is justification for suspecting that the intestinal-oral circuit is part of the natural route of spreading infective hepatitis.

Compound Fractures of Femur Treated with Penicillin.—Burns and Young say that when a débridement has been done some days previously the use of penicillin makes it possible to sew up infected and purulent wounds. Penicillin does not have so dramatic an effect on local sepsis as it does on the prevention of its spread, but that prevention is absolute. There were no deaths, no amputations and no septicemia in the 70 cases of fracture of the femur treated by the authors since D day, June 6, 1944. The great majority of patients reached their hospital between the third and the tenth day after wounding. All came in Tobruk plasters, having had débridement of the wound, the wound being left open. Nearly all the patients had had some penicillin before arrival, but the doses in transit varied within wide limits. After twenty-four hours' rest the plasters were removed under anesthesia and the wounds were inspected. Nearly all had a sulfonamide petrolatum gauze pack. Pus in varying degrees was present in most of the wounds. In some the pack had become a plug and was damming up the pus. Complete closure of the skin gave the best chance of early healing and avoidance of bone infection, and whenever possible the wound was thereafter sewed up completely, regardless of the amount of infection present. The suturing was not determined by bacteriologic findings but on anatomic grounds alone. Of 48 cases completely sutured, 40 healed in a month; 4 more healed at three months; 4 failed and had a sinus at three months. Of 17 which could be only partially closed, 11 were healed and 6 had a sinus at three months. Of 5 cases which had to be left completely unsutured 2 were healed and 3 had a sinus at three months. Thus only 4 of the 48 completely sutured had a sinus at three months against 9 of the 22 incompletely closed. Union of these compound fractures ceeds as quickly as in closed fractures or even more qui Penicillin has justified itself in the treatment of comp fractures of the femur. It is expected that from 40 to 50 eventually show no disability from the fractured femur.

*Postmortem Changes in Scrub Typhus. J. D. Hicks.—p. 57.
"Crude Penicillin" Therapy. D. F. Gray and J. V. Duhig.—p 60.

Postmortem Changes in Tsutsugamushi Fever.—account of the postmortem observations in tsutsugamushi f presented by Hicks is based on twenty-four necropsies formed by him and on reports of a further eleven de occurring at his hospital. Many organs were examined mi scopically. The main changes following fatal infection with disease were a proliferation of reticuloendothelial tissues the production of large numbers of mononuclear cells, large small lymphocytes and macrophages, and some plasma c Most organs were infiltrated by these cells, which were fo mainly in the interstitial or connective tissues. The heart lungs appeared to be most affected by this infiltration. Sepa tion of individual muscle fibers was pronounced in some hea The pulmonary congestion and capillary damage with co quent hemorrhage and production of "heart failure" cells w associated with consolidation. Acute bronchopneumonia sometimes superimposed on this. The liver was congested, little fatty degeneration was present. Toxic changes were p nounced in the kidneys, where tubular damage was a featu The cellular proliferation throughout the splenic pulp cau consistent enlargement of the organ. Vasculitis was promine in the spleen. There was a general swelling of the capilla endothelium throughout the body. There was little eviden that failure of the vital centers of the brain was the immedi cause of death.

*Report on an Outbreak of Epidemic Diarrhea of the Newborn. Kate Campbell.—p. 79.

Epidemic Diarrhea of the Newborn.—Campbell repo an epidemic of diarrhea of the newborn in Melbourne duri 1943. Three attacks occurred, the first in the premature babi ward at the Women's Hospital, the second among the pr mature and full time babies at the Queen Victoria Hospit and the third in the premature ward at the Women's Hospit The season was late fall and winter. The first outbreak w well established before it was recognized, and 9 of the 11 pr mature infants died. In the second outbreak, in which both fu time and premature infants were affected, the full time infan were not as seriously affected as the premature infants. T treatment consisted of initial starvation, free fluids orally, flui given by the parenteral route and sweetened condensed milk The results in this series were much better. Of 8 prematur infants, 2 died. The 20 full time babies all recovered. Sulfa thiazole had no influence on the course of the disease. In th third outbreak sulfaguanidine was used and appeared to pro vide a means to control the disease. Eight of 10 premature infants in this group recovered. The control measure consiste in maintaining three nurseries with separate staffs: (1) th isolation ward into which all babies suffering from diarrhe were placed, (2) the original nursery, where the infants presen at the outbreak were kept till their discharge from hospital and (3) the "clean" nursery, in which all babies born subse quent to the outbreak were placed. Making this disease notifi able would be a safeguard to the newborn infant, provided th typical character of the stool was appreciated; otherwise the reporting of all cases in which loose stools were passed would create an impossible situation.

Hepatorenal Syndrome in Trauma of Liver.—Fenster reports 4 instances of subcutaneous rupture of the liver in men between the ages of 18 and 42 who were admitted to the surgical clinic of the University of Giessen. A pronounced increase in the nitrogen of the blood and the presence of abnormal constituents in the urine were observed in all 4 cases, but a condition resembling that of hyposthenuria was found in only 1 case. A constant increase in the specific gravity of the urine or considerable variations in the specific gravity of single specimens or of daily values were demonstrated in the 3 other cases. Clinical and experimental studies revealed that renal parenchymal lesions may result from trauma to the liver parenchyma. These renal changes were somewhat different from those present in diseases of the liver or gallbladder. They resembled lesions seen after intraperitoneal transplantation of liver tissue or after administration of suspensions of liver cells or of liver autolysates. This may be explained by the disintegration of liver tissue which results from the rupture of the liver due to traumatic force or in gunshot injuries of the liver. The high mortality rate of injuries of the liver cannot be reduced by improved surgical methods or by blood transfusions. An unfavorable postoperative course may be prevented by early diagnosis of the renal disorder. Treatment with insulin and glucose, combined with venesection and blood transfusion, proved satisfactory. Subphrenic abscess frequently occurs; early diagnosis, incision and drainage and blood transfusions are indicated.

*Intra-Arterial Injection of Sulfonamide Preparations in Craniocerebral Injuries. V. V. Kovanov.—p. 29.

Intra-Arterial Injection of Sulfanilamide in Craniocerebral Injuries.—Kovanov demonstrated the permeability of capillaries and the direct action of sulfanilamide on inflammatory foci in the brain by injecting into the carotid artery a sulfanilamide solution together with 0.5 per cent solution of methylene blue. The side of the face and the head became discolored. This was particularly pronounced in the sclera, the mucosa of the tongue and the discharge from the cerebral wound. Smears from the brain lesion taken at five, ten and thirty minute and one hour intervals showed discoloration of the brain tissue. The author injected from 30 to 40 cc. of 1 per cent sulfanilamide solution into the carotid artery in an upward direction in 20 patients with penetrating craniocerebral wounds. From six to eight injections every other day were given as prophylaxis against infection in craniocerebral injuries. The usual surgical principles of treatment of cerebral wounds were adhered to. This prophylaxis prevented the development of a grave infection in almost all of the cases. There was noted a rapid drop of fever, improvement in the general condition and return of appetite and of normal sleep. Focal signs such as paresis and pathologic reflexes regressed or completely disappeared. No instance of the meningeal syndrome was observed. The author treated a group of 30 patients with craniocerebral injury complicated by meningeal symptoms and signs of lesions of the brain. After proper surgical treatment of the wound, these patients were likewise treated by intra-arterial injection of sulfanilamide solution. In the majority of the cases the meningeal process was arrested and signs of focal infection regressed. Five patients in this group died despite this combination therapy. These were severe cases with considerable destruction of brain tissue. Death was caused by a diffuse leptomeningitis in 2, by basal meningitis in another 2 cases and by brain abscess in 1. The author believes that the intra-arterial method of administering sulfanilamide is superior to the intravenous or intramuscular.

Neurologic Symptoms in Wound Sepsis. M. B. Eidinova.—p. 28.

Combined Vitamin Therapy and Liver Function in Sepsis.—Rufanov and Stepanyan observed the effect of polyvitamin therapy on the liver function of 150 patients, 80 of whom presented sepsis or cachexia from wounds while 70 presented local suppurative processes or frostbite. The functional studies included Quick's determination of hippuric acid in the urine, determination of albumin and of the albumin coefficient in the blood serum, determination of the prothrombin in plasma and the glycemic curve. Patients with sepsis in the hyperergic phase showed alteration in the detoxifying function of the liver as expressed by diminished elimination of hippuric acid, namely 21.1 to 35.7 per cent instead of the normal 70 to 80 per cent. The blood prothrombin content amounted to 35 to 45 per cent instead of the normal 70 to 80 per cent. The serum albumin was diminished by 25 to 40 per cent. The albumin-globulin ratio was altered, with an increase in the globulin and diminution of the albumin coefficient. The glycemic curve was distinctly pathologic in the majority of cases, with a rapid rise and a failure to return to the initial level after two and one-half hours. None of the tests displayed a specificity for any of the clinical states. Thirty-two control patients not given vitamin therapy and corresponding in every respect to the vitamin treated group were subjected to the same tests. Comparison of the results obtained suggests that the improvement as demonstrated by the various tests was due to the polyvitamin therapy. Microscopic studies on 25 necropsies, of which 12 were of the control group, supported the biochemical studies of liver functions. Apparently the methods employed are specific for liver function. The authors now perform the test for the detoxifying function of the liver before subjecting a patient to a major operation, except in emergencies.

*Changes of Nervous System in Tularemia. I. R. Dobrinsky.—p. 15.

Alterations of the Nervous System in Tularemia.—Tularemia is manifested in its acute stage by persistent headaches and by pains in the muscles, joints, bones, the back and not infrequently along the course of nerve trunks. The patients as a rule are apathetic and not infrequently somnolent. A number of complications on the part of the central, peripheral and vegetative nervous systems take place. The more frequent of these are radiculitis, neuralgias, neuritides, acute infectious polyneuritis, meningitis, myelitis, encephalitis and trophic lesions of the skin. Meningitis was usually observed in the course of the first week of the sickness, myelitis during the second to fourth weeks, while polyneuritis developed in the late stage of the disease, in the second month or later. Tularemic meningitis had a rapid and rather mild course. Myelitis, neuritis and polyneuritis were characterized by a prolonged course. Dobrinsky did not succeed in a single instance of tularemic meningitis in demonstrating the causative agent in the cerebrospinal fluid. Postmortem studies confirmed the existence of tularemic encephalitis, meningitis and myelitis.

*Investigation on the Passage of Sulfathiazole Through the Blood-Spinal Fluid Barrier in Various Forms of Meningitis. A. H. Andersen and M. H. Simesen.—p. 103.

Blood-Spinal Fluid Permeability Quotient of Sulfathiazole in Meningitis.—It has been previously suggested that the ratio between the concentration of sulfathiazole in the cerebrospinal fluid and in the blood may be a means of distinguishing between a tuberculous and a serous meningitis. Experiments carried out on patients with mild infectious diseases, predominantly measles, and on normal persons revealed that the blood-spinal fluid permeability quotient after the ingestion of sulfathiazole ranged from 0.12 to 0.22, with a mean value of 0.17. The quotient was the same for adults and for children. On examination of 10 patients suffering from tuberculous meningitis an increase in the quotient averaging 0.42 was found in all cases, ranging from 0.32 to 0.55. In 9 patients suffering from secondary lymphocytic meningitis a normal quotient was found (mean value 0.18, varying between 0.14 and 0.23). In 9 cases of primary lymphocytic meningitis a moderate increase was found in 2 severe cases. The increased quotient, however, dropped to normal in the 2 cases kept under observation until recovery. The remaining cases showed a normal quotient. In 4 patients with polyradiculitis a slight increase was found and there was a slight or no increase in 5 patients with poliomyelitis. In 8 patients with purulent meningitis there was a considerable increase in the blood-fluid permeability quotient. But the changes in permeability with a mean value of 0.33 were not so radical here as in the more severe type of meningitis, the tuberculous meningitis which showed a mean quotient of 0.42. It appears that in patients suffering from lymphocytic meningitis an essential and protracted increase in the quotient (above 0.30) is a strong indication that the meningitis is of a tuberculous nature.

Continued Investigations on Histamine in Feces. G. Myhrman.—p. 300.

Recovery from Diabetes Mellitus.—Goadby's criteria of recovery from diabetes mellitus are that on a normal unrestricted diet and without receiving insulin the patients are free from symptoms and have a normal carbohydrate metabolism. The latter is proved by absence of glycosuria and by a blood sugar which, regardless of the carbohydrate intake, at no time of the day rises above 180 mg. per hundred cubic centimeters and shows a normal sugar tolerance curve. Eight patients at the diabetic clinic of St. Thomas's Hospital in London, each of whom had one or more acute attacks of severe diabetes mellitus, presented the complete syndrome of thirst, polyuria, loss of weight and strength, with hyperglycemia, glycosuria and acetonuria. Only three of the attacks were precipitated by a known infection; in the rest a thorough clinical examination failed to reveal any inflammatory or endocrine disturbance, nor did any evidence of such lesions appear later. Recovery from the disease to normal was observed in all these cases. This suggests that there may be many more cases of temporary diabetes than is realized, because the continued good health and satisfactory chemical tests in patients having insulin and/or controlled carbohydrate diet may mask the fact that they have really recovered from their disease. Evidence of the dissociability of the symptoms of diabetes from the metabolic disturbance is afforded by the fact that in elderly patients hyperglycemia and glycosuria need not be associated with symptoms; in a few such cases there may even be ketonuria. Further evidence of dissociations of the symptom complex from the metabolic disorder may be seen in a second series of 9 cases reported by the author. In the patients between the ages from 52 to 64 with persistent symptomless hyperglycemia and glycosuria the classic symptoms of severe diabetes mellitus came and went without apparent change in the carbohydrate tolerance. The symptoms disappeared while the abnormal sugar metabolism persisted. In some of these cases most of the symptoms had disappeared before treatment was begun. Although it is not the author's intention to advocate that diabetes in patients over the age of 50 should not be treated, these cases serve to emphasize the difficulty in assessing the results of treatment.

*Mode of Action of Sulfathiazole and Its Relation to Reticuloendothelial System. U. Borell and L. Troell.—p. 587.

Plasma Proteins and Serum Dialysates in Shock Therapy.—Volkert and Astrup produced shock in rabbits by bleeding the animals from the femoral artery. Dialysates were prepared from ox serum. The animal was first given a transfusion with homologous plasma. There was an abrupt rise of blood pressure from 40 mm. to 90 mm. of mercury followed by a slow, gradual rise to about 110 mm. The blood pressure remained constant at this level for several hours. Rapid injections of dialysates of serum or plasma likewise produced an abrupt rise of blood pressure up to 80 mm. of mercury, but here the effect was brief, the rise being followed within a few minutes by a fall, reaching the initial level in about forty minutes. A solution which contained only proteins of citrated rabbit plasma, while all the low molecular substances have been removed by precipitation and dialysis, was used in additional transfusion experiments on rabbits. It was found to have almost the same effect as that of ordinary plasma transfusion, producing a high constant blood pressure of about 100 mm. Serum dialysates are ineffective in shock. A good effect may be obtained from the administration of the isolated and purified plasma proteins.

Sulfathiazole and Reticuloendothelial System.—Borell and Troell studied the mode of action of sulfathiazole and its relation to the reticuloendothelial system in guinea pigs. Trypan blue was used to demonstrate the phagocytic power of the drug. Animals were given a single dose of trypan blue after having been subjected for some time to injections of sulfathiazole. Only trypan blue injections were given to control animals. In a second experiment pieces of liver and omentum were removed from guinea pigs four days after the injection of trypan blue. Twenty days later, when the trypan blue solution could be expected to have been eliminated, the animals were injected intraperitoneally with sulfathiazole in large doses daily for ten days. Both control and test animals were killed four days after a repeated injection of trypan blue. In the third experiment sulfathiazole was injected subcutaneously into the abdominal region of the animals in order to produce a strong local effect on the reticuloendothelial system. Trypan blue was injected in the same places a few days later. Only trypan blue was administered to the control animals. Results were as follows: Sulfathiazole administered intraperitoneally increased the amount of trypan blue granules in the macrophages of the omentum. In other organs of the reticuloendothelial system, the liver, spleen, bone marrow, lymphatic glands and thyroid gland, sulfathiazole did not produce any pronounced or uniform change in the quantity of absorbed color. The experiments proved that sulfathiazole cannot "block" the reticuloendothelial system.

Book Notices

A Manual of Tropical Medicine Prepared Under the Auspices of the Division of Medical Sciences of the National Research Council. By Colonel Thomas T. Mackie, M. C., A. U. S., Executive Officer, Tropical and Military Medicine, Army Medical School, Major George W. Hunter, III, Sn. C., A. U. S., and Captain C. Brooke Worth, M. C., A. U. S. Cloth. Price, $6. Pp. 727, with 287 illustrations. Philadelphia & London: W. B. Saunders Company, 1945.

This book is the product of wide collaboration by military authorities in the field of tropical medicine and was prepared under the auspices of the division of medical sciences of the National Research Council. Although it was designed primarily for the use of medical officers of the armed forces in the field, it should find wide usefulness in the laboratories and schools and serve as a convenient summary of up to date information for physicians and other public health workers.

During the past few years, when the exigencies of universal war have brought about the movement of large masses of men into tropical zones, the health problems arising from it have been prodigious. A considerable amount of enlightenment and definite changes of concept have resulted. We can no longer consider diseases formerly classified as "tropical" to be alien to our temperate zones, for literally millions of returning men will be placing them squarely on our doorsteps. The geographic barriers of exotic diseases will continue to be infiltrated by stepped-up commerce to the end that we shall encounter these hitherto unusual problems with greater and greater frequency.

The need for improvement in our general understanding of tropical medicine and the need for added stress of the subject in our medical schools are great. The authors have made an important contribution. The book is divided into eleven sections, on the viruses, rickettsial diseases, spirochetal diseases, bacterial diseases, mycotic diseases, protozoal diseases, helminthic diseases, nutritional diseases, miscellaneous conditions, medically important arthropods and laboratory diagnostic methods. Each section is treated in outline form, and the individual diseases are discussed under the headings of synonyms, definition, distribution, etiology, epidemiology, pathology, clinical characteristics, diagnosis, treatment and prophylaxis.

The text is concise but more generous than one encounters in most manuals or compendiums. There is a gratifying profusion of illustrations which have been nicely reproduced from photographs, photomicrographs, drawings and charts. The section on malaria which is, quite understandably, in considerable length and detail, contains six color reproductions of drawings of malarial parasites. Wherever possible, epidemiology has been clearly pictorialized by figure diagrams.

The section on laboratory diagnostic methods is particularly excellent in its clear and simple presentation of procedures designed for employment in the field, small laboratory or office. As a whole the manual is an admirable, authoritative, up to date working book and a timely companion volume for the standard textbooks on the subject. The omission of bibliographic references from the text may seem regrettable but was deemed advisable by the authors in order to conserve space and paper. The book is sturdily bound in cloth and well printed on durable glazed paper. The index, which is frequently omitted from books thus designed and organized, is complete and leaves little to be desired for rapid reference.

Essentials of Oral Surgery. By Vilray Papin Blair, A.M., M.D., F.A.C.S., and Robert Henry Ivy, M.D., D.D.S., F.A.C.S., Professor of Maxillo-Facial Surgery in the Graduate School of Medicine, University of Pennsylvania, Philadelphia. With the collaboration of James Barrett Brown, M.D., F.A.C.S., Associate Professor of Clinical Surgery in the School of Medicine, Washington University, St. Louis. Third edition. Cloth. Price, $6.50. Pp. 624, with 467 illustrations. St. Louis: C. V. Mosby Company, 1944.

It is well to remember that this book is intended chiefly as a guide in surgery to the dental student. The book admirably fulfils its primary object. Of necessity, much of the text is elementary. It seems advisable to include under surgical precautions that no patient should be operated on unless there has been a complete and thorough history and examination to eliminate possibility of cardiorenal disease, blood dyscrasias and diabetes because such conditions require special preparations for surgery. Too few dentists take this precaution. The section on fractures of the jaws is by far one of the best features of the book. It contains the most essential elements and principles of treatment of injuries of the maxillofacial bones. The illustrations are excellent, but the reproductions of the roentgenograms are not as clear as they might be. The authors are to be commended for including the subject of "snapping jaws" or chronic recurrent subluxation. This condition has been the bane of most men engaged in this work. Its treatment is difficult, but solution of the problem cannot be accomplished by avoiding it.

Whereas the value of dental root resection has been questioned by a number of men, this procedure has nevertheless proved of decided benefit in many cases. If the procedure as described here is followed carefully, more beneficial results should be obtained. The section on surgical preparation of the mouth for artificial dentures is exceptionally well done, with excellent illustrations, and should prove of tremendous value to the dental practitioner. For the dental student there might be added to the section on tumors a clinical classification in addition to the excellent cellular classification of Mallory. This chapter may well be read with much value by all surgeons engaged in this field. In the section on congenital facial and palatal clefts the archaic term "harelip" should be eliminated and the descriptive term "cleft lip" substituted. The subject and technic of sialography should be included in the discussion on disorders of the salivary glands and ducts. There is sufficient proof that this procedure is definitely beneficial as a diagnostic procedure and has therapeutic value in nonspecific inflammatory lesions. The beneficial effects of roentgen rays in the treatment of certain types of inflammation is also a proved fact. In the discussion on carcinoma of the lip a most significant statement is made; to wit, "We have no right to assume that because the lymph nodes are not palpable they are not infected."

This is an excellent textbook for dental students.

The Abortion Problem. Proceedings of the Conference Held Under the Auspices of the National Committee on Maternal Health, Inc., at the New York Academy of Medicine, June 19th and 20th, 1942. Howard C. Taylor Jr., M.D., Conference Chairman. Editorial Committee: Nicholson J. Eastman, M.D., Earl T. Engle, Ph.D., and Raymond Squier, M.D. Cloth. Price, $2.50. Pp. 182, with 3 illustrations. Baltimore: Published for National Committee on Maternal Health, Inc., by Williams & Wilkins Company, 1944.

It augurs well for medical and social thinking that physicians, jurists and social workers foregathered in a two day conference to discuss the problem of abortion. The calling of such a conference would have been tabooed in 1920. The conference occupied itself with both voluntary and involuntary abortion. New light was not shed on the etiology and treatment of this condition, with the exception of Dr. Philip Levine's discussion of the Rh factor as a possible cause in spontaneous abortion. The reports on frequency of abortion by P. K. Whelpton in the Indianapolis survey and the statistical study by Halbert A. Dunn are illuminating. Their estimate of the number of abortions in the United States is probably too low. Surely the ratio of one abortion to every five confinements even in the rural districts is too low an estimate. Taussig's calculation of 734,000 abortions in 1940 is also an underestimate, as indicated by Kopp's studies that in some instances the ratio is one abortion to 2.5 confinements.

The atmosphere of the conference apparently was highly charged when the problem of criminal abortion was discussed. Jurists accused the medical profession of failing to assume leadership, and this was bluntly pointed out by Magistrate Anna Kross when she said "it is fallacious to look to the courts or the legislature for the solution of this abortion problem." The interprofessional relationship concerning criminal abortion was well summed up by Dr. Sophie Kleegman in discussing Mr. Black's paper, when she said "the doctor says it is the lawyer's fault and the jurist maintains that it is up to the medical profession to state the indications for abortion. The doctors, on the other hand, say that they cannot get their bill passed by the legislature, whereupon the lawyers say it is the fault of the church."

The conference apparently was so absorbed with the social and moral aspects of the abortion problem that it failed to give due consideration to some of the eugenic phases of criminal

abortion, such as pregnancy induced through incest, pregnancy in the imbecile and defective and pregnancy induced by rape of young girls. Surely some constructive suggestions, how to deal with these cases, should have emanated from such an important conference. Even the problem of illegitimate pregnancy was lightly touched.

While one cannot agree with F. W. Stella Browne that "woman's right to abortion is an absolute right—abortion should be available for any woman without insolent inquisitions or ruinous financial charges, for our bodies are our own," or the other extreme, the religious concept that the induction of abortion is not justified under any circumstances, still one gets the impression from reading the proceedings of the conference that it had not been stripped of the supernatural taboos surrounding the problem of abortion, that it did not reach a high intellectual level in at least making some definite suggestions in connection with pregnancies which occur as a result of abnormal sex behavior or violence.

In that respect it is disheartening to learn how little new the social workers have contributed to the conference proceedings. Probably Algernon D. Black was correct when he stated that "the situation with regard to abortion is a humiliating one" and therefore it is cautiously dealt with. That attitude was further substantiated by Dr. Robert L. Dickinson's query "With all the research material available, we talk statistics, speculate on theology and morals, and we do not get down to brass tacks; when are we going to do it?"

Physicians, lawyers and social workers will find some interesting facts and statistical data in connection with the abortion problem, and the proceedings should be read by those who are interested in progressive and social problems affecting the well being of the nation.

Mass Miniature Radiography of Civilians for the Detection of Pulmonary Tuberculosis (Guide to Administration and Technique with a Mobile Apparatus Using 35-mm. Film: and Results of a Survey). By Kathleen C. Clark, P. D'Arcy Hart, Peter Kerley and Brian C. Thompson. Medical Research Council Special Report Series No. 251. Paper. Price, 90 cents; 3s. Pp. 135, with illustrations. New York: British Information Service; London: His Majesty's Stationery Office. 1945.

This is a report of the findings of miniature x-ray inspection of the chests of approximately 23,000 persons from two factories, a large office group and a hospital for the mentally ill, all located in Greater London. Section one of the first part contains a discussion of the various methods employed in mass radiography. Those who have used photographic paper extensively in this country will probably disagree with most of the disadvantages listed for this method. On the other hand, those who have found the 35 by 35 mm. photofluorogram the least satisfactory method will disagree with most of the advantages offered for this method in adopting it as the one of choice. The x-ray inspection of the chest was on a voluntary basis. In one factory (A) 90 per cent of the total employees available during the inquiry responded, in the other factory (B) 39 per cent, among the office workers of fifteen government departments in London 62 per cent. In a hospital for the mentally ill, 89 per cent of all the patients and 43 per cent of the total resident and nonresident staff had x-ray inspection.

Among factory and office workers it was found that hospital or sanatorium capacity would be required for three or four per thousand, and dispensary supervision only for ten per thousand. Obviously this procedure is good, since one is dealing with a contagious disease. However, it has definite limitations. 1. Even if 95 per cent of any large office or factory group responded there could still be in the remaining 5 per cent many persons who suspected or actually knew that they had tuberculosis but who avoided having it become known to their employers or health authorities. 2. Among those who responded, a vast majority had no evidence of pulmonary disease of any kind. A considerable number of these persons may have lesions evolving which have not yet reached macroscopic proportions. While this is understood by the physician, the fact that no abnormality is found on the x-ray film is likely to result in a false sense of security, and such individuals are not likely to appear for many annual inspections. If all these persons were to receive the tuberculin test there would be a good basis on which to convince the reactors that they should have x-ray inspection of the chest at least annually. 3. In parts of the world where the incidence of tuberculous infection is low the number of cases found by mass radiography is too small to sustain the interest even of those doing the work. In such places it is far more profitable to inspect with x-rays annually or more often only the chests of the adult reactors to tuberculin, where practically all of the cases of clinical tuberculosis develop.

The authors have done a large volume of work and have made worthwhile observations. Their material is well presented, and the book will be found of great value in places with a high incidence of the disease where mass radiography is applicable.

Approved Laboratory Technic: Clinical Pathological, Bacteriological, Mycological, Virological, Parasitological, Serological, Biochemical and Histological. By John A. Kolmer, M.S., M.D., Dr.P.H., Professor of Medicine in the School of Medicine and the School of Dentistry, Temple University, Philadelphia, and Fred Boerner, V.M.D., Associate Professor of Clinical Bacteriology, Graduate School of Medicine, University of Pennsylvania, Philadelphia. Fourth edition. Cloth. Price, $10. Pp. 1,017, with 346 illustrations. New York & London: D. Appleton-Century Company, Inc., 1945.

A new edition of this manual of laboratory methods as usual arouses interest and favorable comment. The collaborators now number thirty in addition to the two authors. This wartime edition, brought out in compliance with government directives limiting the bulk of paper, has resulted in a new format which nevertheless compares favorably with previous editions. There is an excellent index of fifty-eight pages, though too much space has been given to the table of contents at the beginning of the book. An innovation, not entirely pleasing if not actually disconcerting, has been the omission of numbered sections and chapters. The illustrations are good for the most part, and although they number twenty-four less than in the preceding edition the omission of several obsolete cuts has permitted the addition of many new instructive figures and plates. In the new section on the examination of feces more care should have been given to the legends, in which the nomenclature does not always conform to that found in the text. Among the new methods included are those for the examinations for hormones and for vitamins in blood and urine. Also considerable space is given to interesting material on mycologic and virologic methods. Clinical pathologists and medical technologists will find this a useful laboratory aid, dedicated as formerly "to those who have advanced the science of clinical pathology and in memory of Ward Burdick, M.D., founder of the American Society of Clinical Pathologists."

Textbook of Surgical Treatment Including Operative Surgery. Edited by C. F. W. Illingworth, M.D., Ch.M., F.R.C.S.E., Regius Professor of Surgery, University of Glasgow. Compiled by nineteen contributors. Second edition. Cloth. Price, $9. Pp. 564, with 230 illustrations. Baltimore: William Wood & Company, 1944.

The appearance of the second edition of this work less than eighteen months after the first, particularly during a war period, must be indicative of the demand for and the popularity of the book. As its title indicates, it is truly a textbook of surgical treatment and not only of operative surgery. In addition to descriptions of operative technic, it covers all other forms of surgical care, including radiotherapy. Special attention is devoted to the choice of treatment, to the indications for and against operation and to the dangers and complications which may arise. An enormous amount of material and information is included in the book, which is divided into thirty-seven chapters. The entire field of surgery, including neurosurgery, orthopedics and urology, is covered quite well, though rather briefly at times. It is the work of nineteen contributors, who represent the schools of Glasgow, Edinburgh and Aberdeen. Their views are up to date and correspond well with those accepted in this country. The author deserves credit for the simplicity and clarity of style as well as for the large number and variety of topics included. The illustrations are well selected, appropriately placed and well reproduced. They enhance the value of the text. The physical makeup of the book is also excellent for this period, and the publishers are to be congratulated on the high quality of production. The book, which is intended for senior students, may also prove to be of value to instructors and may be recommended unhesitatingly to those for whom it has been prepared.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

TREATMENT OF AGRANULOCYTOSIS

To the Editor:—Is there anything new in the treatment of agranulocytosis? The patient has had large doses of pentnucleotide, reticulogen and yellow bone marrow intramuscularly. L. S. Pederson, M.D., Manhattan, Ill.

ANSWER.—The usually accepted treatment for agranulocytosis includes the use of multiple whole blood transfusions, particularly if the patient has any degree of anemia; large doses of pentose nucleotide intramuscularly; liver extract intramuscularly, and yellow bone marrow by mouth. Most patients with the disease have been treated by one or more of these four agents. More recently there have been reports of the successful treatment of the disease by one of the sulfonamide compounds or by penicillin, particularly in patients who show clinical evidence of sepsis. This treatment is based on the concept that the infectious state that usually accompanies or follows the disease is a more important therapeutic problem than the bone marrow suppression per se. One of the most important measures of treatment is the establishment of the cause of the disease, if possible, and the taking of precautions that the patient does not come in contact with the causative agent. If the causative agent should be one of the sulfonamide drugs, then other sulfonamide drugs can be used in treatment. The question indicates that the patient has had a thorough trial with pentose nucleotide, liver extract and bone marrow. Since typical agranulocytosis is usually a disease of short duration, it should be clearly established that the patient does not have another leukopenic disorder, such as leukemia in an aleukemic phase.

SCHEMM TREATMENT OF CARDIAC EDEMA

To the Editor:—There is in this locality a great deal of argument, pro and con, as to the merits or demerits of the so-called Schemm treatment of chronic heart failure with edema. This therapy is referred to in the *Annals of Internal Medicine* (17: 952 [Dec.] 1942) and in the *Archives of Internal Medicine* (73: 138 [Feb.] 1944). These reports of great numbers of patients with cardiac edemas successfully treated by high fluid intakes appear quite convincing. I would like to have a critical estimate of its value and to know whether or not its acceptance is increasing.

M.D., Illinois.

ANSWER.—The Schemm diet, introduced in the treatment of congestive heart failure with edema, is proving to be an important contribution to our therapeutic armamentarium. Although used in many cases and for quite a few years by Schemm himself and by a few others for a short time, it has been slow in trial and adoption by the larger clinics—a situation that is common in medical practice partly because of a state of inertia based on classic tradition and partly because of the distraction of interest and opportunity by the current war. In one form or another this method, however, has been in use in several clinics like that especially of Newburgh at Ann Arbor, Mich., and of Ellis at the Boston City Hospital, but it has been little publicized. A series of cases is at present being treated promisingly at the Massachusetts General Hospital and will be reported later.

The treatment consists, in brief, in the use of a diet that has a neutral or acid and not alkaline ash, very low in content of sodium chloride but with ample fluid intake; in fact, Schemm has advised forcing fluids even to the amount of 4 liters or more a day, which is apparently unnecessary in most cases, 2 to 3 liters sufficing to establish an adequate diuresis and a relief of the intense thirst so often a distressing symptom in patients with anasarca who have been very limited in fluid intake (e. g. 1 liter in twenty-four hours). An important part of the therapy includes the administration of considerable ammonium chloride (3 to 9 Gm. daily) and even of hydrochloric acid (which is, however, less effective). For many cases the diet is unpalatable and difficult to take, but most patients become used to it and prefer it to the distressing thirst and edema. It is the production of an acidosis that leads to the diuresis, and the limitations of such a state, in renal insufficiency for example, have not yet been adequately explored. The Schemm diet has, in some patients at least, obviated the need of vigorous mercurial diuretics and therefore in this particular too has been gratefully adopted by edematous cardiac patients. For details of the diet itself the reader is referred to Schemm's papers.

ADAMS-STOKES SYNDROME

To the Editor:—A woman aged 58 has suffered attacks of Adams-Stokes syndrome for the last six years. The attacks are sometimes preceded by pain over the heart radiating into the left arm, characteristic of angina pectoris, and sometimes by a slow and irregular heartbeat; sometimes they come on without any premonitory symptoms. Four months ago the patient had a severe attack preceded by pain over the heart; bradycardia followed for ten days, during which time Adams-Stokes attacks with complete cessation of the heartbeat and unconsciousness occurred about five times a day. The physical examination, blood count and blood chemistry revealed nothing significant. The size of the heart is normal; there are no murmurs. Blood pressure is 110/70 between attacks. The Wassermann reaction is negative. The electrocardiogram shows a complete auriculoventricular block 3 to 1 during the attacks. Between attacks the electrocardiogram reveals left bundle branch block and first degree auriculoventricular block (PR 0.22 second). Treatment has been aminophylline 0.24 Gm. intravenously or by rectum every six to twelve hours, belladonna tincture up to tolerance, which is 15 drops three times a day, and estrone 2,000 units daily. During the attacks she receives papaverine 1 grain (0.06 Gm.) intravenously, atropine sulfate 1/150 grain (0.0004 Gm.) subcutaneously and glyceryl trinitrate if the attack is preceded by angina pectoris, and as a last means, when her condition is desperate, epinephrine or ephedrine. Barium chloride was used for only a few days because it seemed to aggravate her condition. At present her condition is fairly good, as she suffers from Adams-Stokes attacks only once a month. However, the heart rate is liable to drop to around 40 every morning, and especially after meals in spite of atropine administration before and during meals, bed rest and excellent care of three trained nurses. Naturally she is very much discouraged by the outlook; to lead the rest of her life with the continuous dread of another attack. Has the section of one vagus nerve ever been tried for this condition? If not, would it be theoretically justified to try it for the first time in my patient? If so, which vagus nerve should be severed? What other treatment is suggested?

M.D., Maryland.

ANSWER.—Adams-Stokes attacks produced by ventricular standstill in high grade auriculoventricular block are generally the result of coronary heart disease and should apparently be so considered in this patient. The presence of the left bundle branch block supports this interpretation, because in cases of coronary heart disease bundle branch block and auriculoventricular block are not infrequently associated. The PR interval of the electrocardiogram between syncopal attacks is sometimes not much prolonged (as noted in this case it is only 0.22 of a second); it is indeed possible to have the Adams-Stokes syndrome due to high degrees of periodic auriculoventricular block with a normal PR interval time between the attacks. Local anoxia or infarction dependent on coronary obstruction is the cause of the defect, often producing no other symptoms or signs; but occasionally clinical myocardial infarction of a major sort, especially that occurring in the posterior wall of the left ventricle, may be attended by temporary and less commonly by permanent or recurrent auriculoventricular block. Rheumatism, syphilis, diphtheria and congenital defects are uncommonly causes of chronic or recurrent heart block of high degree. Complete heart block is not viewed as synonymous with 3 to 1 block, as indicated in the description given, although the ratio of auricular to ventricular heart rates may be approximately 3 to 1; 3 to 1 block should be referred to only when there is a direct auriculoventricular association.

The prognosis of Adams-Stokes attacks must always be regarded with considerable uncertainty. In other words, it must be guarded over the period, which may extend for months or even years, during which the Adams-Stokes attacks occur. In a good many cases the block finally becomes stabilized at a complete auriculoventricular block level with idioventricular rhythm; in fact, that is much more likely than the permanent restoration of normal rhythm. Once this complete auriculoventricular block is well established, the prognosis may be good for years to come without any therapy at all. Some patients do, of course, die from cardiac standstill or complications during the period of recurrent Adams-Stokes attacks. This period is unusually long in the case referred to in the query.

Treatment of Adams-Stokes attacks, particularly in the way of preventing attacks, is unsatisfactory except through the use of epinephrine (0.5 to 1 cc. of 1: 1,000 epinephrine hydrochloride subcutaneously every few hours, as needed; a more prolonged effect is obtained if given in oil, in which case only one or two injections a day may be necessary). As a rule various other drugs, which include atropine and belladonna, aminophylline, papaverine, the nitrites, thyroid and barium chloride, are unsatisfactory, although on occasion atropine, aminophylline and the nitrites have decreased the grade of block in the case of lesser grades of heart block secondary to coronary insufficiency. Vagotonia is not, in most cases, an important factor, although it may be a superimposed influence of some significance. In general, since experience with atropine has shown disappointing results, vagal section would probably not be helpful. Ephedrine and similar preparations are fairly good substitutes for epinephrine when the attacks are not severe, but they are less effective in emergency. They have the advantage, however, of being suitable for administration by mouth.

FREQUENCY OF PERFORATION OF DUODENAL ULCER

To the Editor:—Recently a man aged 30 applied to a medical examiner of the Administrator of Civil Aeronautics for a medical certificate required incidental to the issuance of a student pilot certificate. The examination disclosed the presence of duodenal ulcers. Because of this the administrator refused to issue a medical certificate. A hearing was accorded the applicant for the purpose of reconsidering the refusal of the administrator to issue the medical certificate. From the evidence adduced at the hearing it was established that duodenal ulcers may result in a perforation; that the occurrence of a perforation is utterly unpredictable, it being possible for one to occur tomorrow or perhaps not for years or perhaps never; and that when a perforation does occur it suddenly and completely incapacitates its victim. Should such an occurrence take place while one was piloting an aircraft, its potentialities for disaster are obvious. In studying this problem I should like to obtain the best statistics or information available in answer to the question In how many cases of duodenal ulcers do perforations result? If, for instance, it was ascertained from a study of this disease that perforations result in 1 out of 5 cases, that might well be considered a dangerous proportion, but if a perforation was known to result in only 1 out of 500 cases that would be quite another thing.

John H. Woodworth, Examiner, Safety Section,
Civil Aeronautics Board,
Washington 25, D. C.

ANSWER.—A definite figure of the incidence of perforation in duodenal ulcer cannot be given as the number is dependent on two variable factors, namely the activity of the ulcer and the period of time under consideration. The number of perforations in any given group would depend on the proportions of active, healing and healed ulcers and the duration of the period of observation. Hurst and Stewart (Gastric and Duodenal Ulcer, New York, Oxford University Press, 1929) state that the total incidence of perforation is small and cite a report by Nielson in 1922 of 182 patients diagnosed as having ulcer between 1897 and 1917, 42 of whom had undergone some operation between one and twenty years later but none for perforation. Sixteen of the remaining 140 had died between two and a half and twenty years after leaving the hospital, but none from perforation. Hurst and Stewart report also that, in the cases of duodenal ulcer seen by them between 1921 and 1927, 2 out of 130 gave a history of perforation and 1 perforated one year after being in the clinic. Perforation also occurred in 1 other patient in whom no previous signs of ulcer had been found. The Criles (Indications for and End Results of Surgery in the Treatment of Duodenal Ulcer, *Am. J. Surg.* **40**: 123 [April] 1938) report perforation in 8 per cent of 100 ulcer patients treated surgically. Surgical treatment was utilized in 5 per cent of all the cases of ulcer observed in their clinic during the period covered by their report. This is a ratio of 1 perforation to every 250 ulcer cases in their series. Perforation is always possible in ulcer in the phase of active ulceration. Even after the ulcer has healed there is a predisposition to recurrence of the ulcer, so that the possibility of perforation is still present, though more remote. Also perforation may occur without premonitory symptoms, as is strikingly demonstrated by the fact that 25 per cent of the cases that perforate do not show preceding symptoms of ulcer. The possibility of perforation can be reduced to a minimum by adequate treatment of the ulcer until it is healed and continuation of an ulcer regimen to prevent recurrence accompanied by roentgenologic examination at regular intervals for evidence of recurrence.

CAUSES OF NUMBNESS IN ARMS

To the Editor:—A man aged about 30, well developed and healthy, has been complaining of his arms "going to sleep" while working at his trade of tinsmith and also at night. He has to rub them for a while. The numb feelings, which are transient, extend into the hands. Blood pressure is 110/90. General physical examination, including test of the motor reflexes of the arms, revealed no abnormalities.

E. C. McCulloch, M.D., Staten Island, N. Y.

ANSWER.—This numbness probably is unrelated to the occupation of tinsmithing, but examinations should be made for other characteristics of lead and arsenic poisoning, both of which may arise from solder. Other possibilities are alcoholism, anemia and avitaminosis. More remote causes might be influenza or other infections, arthritis or cervical ribs. In recent months Dr. Frederick Slobe of Chicago has associated this general type of manifestation with fibromyositis in the upper back regions lateral to the spinal column. Search should be made for small areas or points of tenderness in the back regions mentioned. Local anesthetics at such sites might effect relief. Other causes of numbness are discussed in the following books:

Barton, W. M., and Yater, W. M.: Symptom Diagnosis: Regional and General, ed. 2, New York, D. Appleton-Century Company, Inc., 1933.

French, Herbert: An Index of Differential Diagnosis of Main Symptoms, ed. 4, New York, William Wood & Co., 1928.

CAUSE OF TARNISH ON SILVERWARE FROM HANDLING

To the Editor:—An apparently normal girl aged 18 complains that any silverware which she handles will, unless cleaned within fifteen minutes to a half hour, turn black in the areas touched. Can you suggest the possible cause and the treatment of this condition? M.D., New York.

ANSWER.—The tarnishing of silver exposed to air is not due to oxidation but probably to small quantities of hydrogen sulfide in the atmosphere. Silver coins may blacken when carried in the pockets of persons who are using sulfur applications. It is possible that this young woman comes in contact with sulfur and uses it without realizing that she does so. Many patients willing to cooperate fully are unable to give correct history of their use of medicines. It would be interesting to determine the hydrogen ion concentration on her fingers and hands. One would anticipate a greater acidity of skin surface than that found in most persons. The silver could be dissolved by the acid, form silver lactate by reacting with the lactic acid in sweat and then be precipitated by the sodium chloride also in the perspiration. Finally, exposure to light would reduce the silver chloride to a dark metallic deposit. Polishing of the silver, of course, would interrupt this chain of events. It is suggested that a search be made for an association with or the presence of sulfur on this young woman. Silver coins carried about her person but not in contact with the skin may be a clue.

Perhaps qualitative chemical tests appropriately devised as with lead acetate solution, which darkens in the presence of sulfide, might prove useful. The patient may be able to circumvent her peculiar reaction on silver by washing the hands with soap prior to handling such metallic articles; the soap would temporarily reduce the intensity of the acid on her skin and would wash away such possible intermediates to the blackened deposits as the lactic acid and sodium chloride in the sweat.

TREATMENT OF ACHONDROPLASIA

To the Editor:—Can any suggestions be offered for treatment of achondroplasia in an 8 year old girl? Other physicians have made diagnoses of mongolism and cretinism, in turn. Administration of thyroid did nothing except speed up an already normal pulse. Would an anterior pituitary growth complex be worth trying?

Alan A. Bassett, M.D., Little Current, Ont.

ANSWER.—To date there have not been any encouraging reports regarding the treatment of achondroplasia. Almost all patients with this condition have received thyroid and a great number have received pituitary fractions of one type or another. Unfortunately, the results continue to be discouraging.

IMMUNIZATION WITH MULTIPLE ANTIGENS

At the request of the Office of the Surgeon General, U. S. Army, the following comment is published on the answer (The Journal, May 5, 1945, p. 63) to the question of Major, M. C., A. U. S., on the advisability of using improvised mixtures of vaccines:

While there is little or no objection on theoretical grounds to the mixing of vaccines, such mixtures are not provided for use in the Army because it is frequently necessary to give an injection or a complete series of a single immunizing agent to an individual or to a large group. The distribution of mixed vaccines would add a number of additional products to the stock at each installation where immunizations are done and would involve considerable wastage.

There are at least three objections to making mixtures of vaccines in the field. One is that errors may occur in the mixing of the agents so that the wrong proportions are obtained. The second is the possibility of bacterial contamination in the process, and the third is the danger that incompatible combinations will be made; e. g., that yellow fever vaccine might be mixed with tetanus toxoid, which would entirely inactivate the yellow fever virus.

In preparing vaccine mixtures there are two alternative procedures: either to utilize the entire contents of the original vials of vaccines or to withdraw measured quantities less than a complete vial. Typhoid, typhus and cholera vaccines as used in the Army are packaged in 30 cc., 20 cc. and 20 cc. vials respectively; hence the minimum amount of the mixture suitable for stimulating doses of each agent that could be made using the entire contents of one typhoid vaccine vial is 250 cc.; and if the mixture was to be used as the first dose of cholera vaccine but a stimulating dose of the other agents, 400 cc. would have to be prepared. The danger of incomplete mixing of the vaccines is obvious. On the other hand, if quantities less than one vial were mixed, considerable sterile glassware would be needed for measuring purposes.

The use of improvised vaccine mixtures requires injection of larger quantities of material in one site than if separate injections were made; e. g., in the mixture of cholera, typhus and typhoid vaccines cited, a volume of 2.5 cc. was required. This volume given subcutaneously in the arm would cause more than the usual degree of trauma and might increase the danger of abscess formation.

THE FLUID AND NUTRITIONAL THERAPY OF BURNS

MEMORANDUM PREPARED BY A COMMITTEE APPOINTED BY DR. ALFRED BLALOCK, CHAIRMAN OF THE SUBCOMMITTEE ON SHOCK:

HENRY N. HARKINS, M.D., CHAIRMAN, BALTIMORE

OLIVER COPE, M.D., BOSTON

EVERETT I. EVANS, M.D., RICHMOND, VA.

LIEUTENANT COMMANDER R. A. PHILLIPS (MC), U.S.N.R. NEW YORK

DICKINSON W. RICHARDS JR., M.D., NEW YORK

The National Research Council and the Office of Scientific Research and Development have authorized the release of this memorandum containing suggestions for the use of oral and parenteral fluids and food in the treatment of burns. To the medical officer who has had experience with the treatment of burned patients it will be evident that the suggested outline is somewhat dogmatic. However, the main purpose of the outline is to aid the medical officer with little or no experience in the management of such cases. It is hoped that the discussion of the rationale for giving the suggested fluids will be helpful as a guide to the recommended therapy. Coincident with this fluid and nutritional therapy, local burn treatment in conjunction with parenteral penicillin and oral sulfonamide therapy should be directed toward the prevention and control of burn sepsis, but the latter items are not dealt with in this discussion, important as they may be.

CATEGORY OF PATIENTS WHO SHOULD BE GIVEN SPECIAL FLUIDS AND FOOD ACCORDING TO THIS OUTLINE

Following damage to the skin by a burn there is a loss of extracellular fluid, including salts and plasma proteins, both into the burned area itself and as a discharge from any denuded surface. With this fluid loss there will be dehydration, a decrease in the circulating plasma volume and hemoconcentration (i. e. apparent increase in the number of red cells in the whole blood).

In mild burns spontaneous ingestion of fluids and food according to the desires of the patient is usually adequate, but in more severe injuries special methods of therapy are necessary to aid convalescence and to save lives. It is generally agreed that in burns which involve less than 10 per cent of the body surface there is not sufficient loss of extracellular fluid to warrant intensive fluid therapy.

Hence this discussion is directed to those patients with more than 10 per cent of the body surface involved by second degree (blistered) or third degree (coagulated or charred) burns. Roughly, then, this outline would be followed in patients with a severe burn of at least one of the following areas: (1) face and neck, (2) dorsal or ventral surface of chest, (3) dorsal or ventral surface of abdomen, (4) one upper extremity, (5) dorsal or ventral surface of one lower extremity. If there is any question as to whether the patient should be included in this category, he should be. Patients with burns involving less than 10 per cent of the body surface and with, in addition, any other injury, particularly wounds or fractures, should be treated as though they were in this category. Exceptions to this statement are (1) head injuries, (2) perforating wounds of the chest and (3) burns of the pharynx, larynx or lower air passages (a face burn should make one suspicious of such respiratory involvement). In these instances excessive fluid administration may bring on pulmonary edema. If many burn casualties are seen, it is often advisable to treat energetically those patients with a large surface area involved (30 to 40 per cent) and then treat the less seriously burned patients as time is allowed; further, in patients with burns weeping much plasma, it must be remembered that they will need internal infusions more regularly than will those patients with burns showing little or no seepage.

The course of the severe and inadequately treated burn patient can be divided into three dangerous phases:

1. *The Period of Shock* (to forty-eight hours after the burn).—The signs of burn shock are often very misleading until just before collapse occurs. Thus, shock is often present when a patient looks and acts quite well. Generalized vasoconstriction may keep the blood pressure at satisfactory levels even though cardiac output is greatly diminished. Therefore in the early hours the presence of shock is to be assumed in all severely burned patients despite a satisfactory clinical appearance. If one waits for cold extremities, cyanosis and collapsed veins, therapy is apt to be ineffective. This period of shock (to forty-eight hours after burn) is also essentially the period of vigorous fluid therapy. Subsequently adequate fluid therapy and vigorous food therapy may be indicated, but in a case treated sufficiently during the first two days there is no routine indication for extensive forcing of fluids after that time.

2. *The Period of Toxemia* (from forty-eight to one hundred and twenty hours, occasionally as late as the third week).—Fever, jaundice, anuria, stupor and delirium and circulatory collapse despite adequate fluid therapy are often associated with this syndrome. With full realization of the inadequate state of our present knowledge of the cause of burn toxemia, it may how-

This article has been released for publication by the Division of Publications of the Bureau of Medicine and Surgery of the U. S. Navy. The opinions and views set forth in this article are those of the writers and are not to be considered as reflecting the policies of the Navy Department.

ever be helpful to consider it tentatively as due to one or more of the following conditions:

(*a*) Inadequate treatment of shock or treatment not instituted early enough with consequent ischemic damage to kidneys, liver or other organs. For example, failure to maintain blood volume by plasma and/or whole blood administration. In other instances loss of electrolytes and fluid from burned surface, also from vomiting and sweating with consequent dehydration and acidosis may be an etiologic factor.

(*b*) Excessive administration of electrolyte (noncolloid) solutions with consequent dilution of plasma proteins to the edema level (less than 5 Gm. of protein per hundred cubic centimeters). This is particularly dangerous if there is associated renal and/or cardiac damage.

(*c*) Accompanying infection of burned areas.

(*d*) It has been suggested that there is absorption from burned tissues of protein products which are "toxic." If this occurs the effect will be minimized by maintaining an adequate blood supply to all the body tissues, i. e., a normal blood volume with normal hemoglobin concentration and adequate renal function.

3. *The Period of Burn Anemia and Hypoproteinemia.*—The anemia and hypoproteinemia develop first during the first seventy-two hours but are usually not evident until the signs of toxicity have largely disappeared. Actual red cell destruction with hemolysis, hemoglobinemia and hemoglobinuria soon after the burn is a cause of early masked anemia. It is likely that failure to maintain nutrition is the most important factor in the production of both and every effort, therefore, should be made to keep the burned patient in nitrogen equilibrium throughout the illness.

CRITERIA TO BE USED AS A GUIDE TO FLUID THERAPY

Fluid therapy in burns should be directed toward two major objectives: (A) rapid replacement of acute deficits and (B) maintenance of daily needs.

A. Rapid replacement of acute deficits:

1. Restoration and maintenance of a normal blood volume.

2. Restoration and maintenance of an adequate hemoglobin concentration (13 to 16 Gm. per hundred cubic centimeters).

3. Restoration and maintenance of plasma protein concentration above 6.0 Gm. per hundred cubic centimeters.

4. Restoration and maintenance of a satisfactory urinary output, usually 100 cc. per hour during the first forty-eight hours.

5. Prevention of dehydration and acidosis. (Determination of plasma bicarbonate concentration by the method of Van Slyke is a useful index of acidosis.)

6. Prevention of salt depletion. (Determination of plasma chloride concentration by the method of Van Slyke may be used to determine approximate salt depletion.)

7. Avoidance of overadministration of electrolyte (noncolloid) solutions by the parenteral route.

B. Maintenance of daily normal fluid and nutritional requirements of water, salt, carbohydrate, protein and other substances.

OUTLINE OF FLUID THERAPY IN BURNS

I. *Early Acute Burns* (up to forty-eight hours): *The Prevention and Treatment of Burn Shock.*—Fluids are given in this phase for three purposes: (1) to restore blood volume and to treat shock (chiefly plasma and blood), (2) to provide extra fluid to compensate for loss from burned surfaces and as edema of injured tissues (plasma and salt solutions) and (3) to provide additional fluid for adequate urinary excretion (water and salt solutions or dilute salt solutions). In a severe burn (30 to 40 per cent of the body surface or more) the volumes involved for the forty-eight hour period are roughly (1) 2,000 cc., (2) 4,000 to 10,000 cc., (3) 2,000 to 3,000 cc. Replacement therapy in the first forty-eight hours thus involves fluid volumes of these magnitudes, totaling 8,000 to 15,000 cc. for the forty-eight hour period. With the larger volumes, close watch should be kept for circulatory congestion.

A. *Intravenous Therapy.*—1. Plasma: Whole plasma is the colloid solution of choice; it supplies fluid and electrolyte as well.

(*a*) The dosage of plasma is best gaged by previously suggested formulas which depend on hemoconcentration, size of burn and, of especial importance, the clinical response of the patient. The depth of the burn is of little practical value as a guide for this purpose.

(*b*) It is best not to give all of the indicated amount of plasma at one time. Even if clinical shock is severe, usually one third of the complete dose is sufficient at first, other equal doses being given over the succeeding four or five hours.

(*c*) When acute collapse occurs, the first dose of plasma should be given rapidly. Since in these circumstances there is an acute failure of venous return to the heart, the fluid introduced must to a considerable extent supply this venous return. An initial introduction of 200 to 300 cc. in the first two minutes is not too rapid; the administration should be continued, up to 1,000 cc. or more, until a satisfactory clinical response is obtained. Subsequent amounts should be given more slowly. In shock, time is extremely important; if plasma or whole blood is not immediately available, give intravenous electrolyte solution (physiologic electrolyte solution or isotonic sôlution of sodium chloride if the former is not available) rapidly until plasma and whole blood are secured. By the term physiologic electrolyte solution is meant a mixture of 2 parts of normal isotonic (one-sixth molar) (0.9 per cent) sodium chloride solution with 1 part of normal isotonic (one-sixth molar) (1.3 per cent) sodium bicarbonate solution. If sodium bicarbonate solution is not available, sodium lactate normal isotonic (one-sixth molar) (1.75 per cent) solution may be substituted. The final mixture is of the following concentration in round numbers: sodium chloride (one-tenth molar, 0.6 per cent, 100 millimols per liter) and sodium bicarbonate (one-twentieth molar, 0.5 per cent, 50 millimols per liter) or, if sodium lactate is used in place of the bicarbonate, sodium lactate (one-twentieth molar, 0.6 per cent, 50 millimols per liter).

(*d*) Plasma is of little value beyond the third day and is seldom needed after the first twenty-four hours if the treatment during that period has been adequate. Its chief role is in large surface area burns (over 10 per cent of the body surface) and during the first forty-eight hours.

(*e*) Technic of intravenous therapy: Insert a large (no. 16 or 18) hypodermic needle into the vein, withdraw 5 cc. of blood, fix the needle in place with adhesive tape and start intravenous fluids. The blood is placed in a test tube containing 5 mg. of a 3:2 mixture of ammonium and potassium oxalate. From this blood sample is obtained the whole blood specific gravity

(see later for method). The remainder is saved for typing and cross matching and if possible a portion is centrifuged or allowed to sediment so that the plasma specific gravity can be determined. After the initial plasma infusion in all patients in whom there is any likelihood of the development of shock or in whom accessible veins are scarce, it is desirable to leave the intravenous infusion needle in place, maintaining its patency with a slow infusion of physiologic electrolyte solution or other available isotonic solution.

(*f*) If superficial arm veins are inaccessible, femoral vein puncture, saphenous vein cannulization in the foot, ankle, leg, or even at the fossa ovalis, or intramedullary injections may be necessary.

Representative Formulas:

(*a*) Formulas dependent on extent of hemoconcentration:

(1) Give 150 cc. of plasma for each specific gravity increase of 0.001 above the normal whole blood specific gravity [1] of 1.060 (i. e., if the specific gravity of whole blood is 1.070, give 1,500 cc. of plasma); (2) or give 100 cc. of plasma for each point the hematocrit exceeds the normal of 45 (i. e., if the hematocrit is 60, give 1,500 cc. of plasma); (3) or 50 cc. of plasma for each point the hemoglobin exceeds the normal of 100, or 300 cc. of plasma for each gram the hemoglobin exceeds the normal of 15 Gm. per hundred cubic centimeters (i. e., if the hemoglobin is 130 per cent or 20 Gm. per hundred cubic centimeters give 1,500 cc. of plasma); (4) or 100 cc. of plasma for each 100,000 the red cell count exceeds the normal of 5,000,000 per cubic millimeter (i. e., if the red cell count is 6,500,000 give 1,500 cc. of plasma).

All formulas based on blood concentration-hematocrit and so on may at times be in serious error. For example, in the first hour or so after the injury the hematocrit may still be normal, plasma loss having just started. In such a case the hematocrit repeated at the third and sixth hours gives a truer picture of the condition. Other patients may be anemic at the time of injury or because of associated wounds. No matter what formula is used, the corresponding dosage for children should be less and is roughly proportionate to the body weight. It should be remembered that formulas dependent on hemoconcentration show only the needs of the patient at the time of testing, not all his requirements during the entire course of the burn.[2]

(*b*) Formula dependent on the area of the burn:

Give 50 cc. of plasma for each per cent of the body surface involved by a deep (blistering) burn during the first twelve hours. Often more plasma must be given later. Burns of the face, groin or buttocks usually lose more plasma than the surface involvement indicates, and more plasma should be given accordingly. Very few persons with less than 10 to 15 per cent of the body surface burned will require plasma transfusions.

2. Albumin: Iso-osmotic human albumin solution is a satisfactory substitute for blood plasma in comparable dosages of protein. With concentrated albumin solutions, saline solution should be given in addition.

3. Whole Blood Transfusions: In patients with a hematocrit below 60, give 500 cc. of compatible whole blood for every thousand cubic centimeters of plasma administered. In any case in which plasma is not available, whole blood is better than intravenous electrolyte solutions.

Rh typing is mandatory in all burn cases which show transfusion reactions on repeated transfusion. It is desirable in all cases of deep burns of more than 20 per cent of the body surface in which repeated transfusions may be needed. The use of Rh negative blood for females under 40 years of age is advisable.

4. Electrolyte Solutions: (*a*) Burns of less than 10 per cent of the body surface: Give 2,000 cc. of physiologic electrolyte solution each twenty-four hours, preferably by mouth; if not, by vein.

(*b*) Burns of more than 10 per cent of the body surface: Chief reliance for prevention or relief of shock is placed on plasma (or albumin or whole blood), as indicated.

However, additional amounts of saline and glucose solutions should also be given parenterally to patients unable to take adequate amounts by mouth or to extensively burned patients in whom the required intake by mouth may be excessive, i. e. more than 8 liters in any twenty-four hour period. The physiologic electrolyte solution or its equivalent should be used. Some of this fluid should also contain glucose, about 100 to 200 Gm. daily. To give average figures, the volume of electrolyte solution given intravenously will be roughly the same as the volume of plasma in the first two days. It will be larger or smaller, depending on the success of oral therapy, but should not exceed 4,000 cc. in any twenty-four hour period.

B. *Oral Therapy.*—As already indicated, oral therapy with crystalloid solutions is chiefly to provide fluid for surface loss and local edema and for adequate urine volume. Water and non-salt containing fluids, such as milk and ginger ale, can be given up to 2,000 cc. a day to aid renal function; no more than this quantity should be given until all of the required electrolyte solution has been swallowed and retained. After this has been accomplished, water can be given ad libitum in controlled and reasonable amounts.

The following suggestions are made for the administration of oral fluids in the first forty-eight hours:

(*a*) Burns of less than 10 per cent of the body surface: Give 2,000 cc. of physiologic electrolyte solution each of the first two days.

(*b*) Burns of more than 10 per cent of the body surface: Give 3,000 to 8,000 cc. of physiologic electrolyte solution the first day, depending on the extent of the burn.

Give 3,000 cc. of physiologic electrolyte solution the second day.

1 Use of the copper sulfate method for determination of specific gravity. This method rapidly and accurately estimates the hemoglobin concentration. Since plasma protein concentration in burns is usually either normal or low (from lost plasma proteins) a specific gravity of the whole blood above 1.060 indicates abnormally high hemoglobin due to deficient plasma volume. With normal or low plasma proteins a specific gravity for whole blood of 1.060 indicates (1) a hematocrit of 45 or more per cent cells, (2) a hemoglobin concentration of 15 or more grams per hundred cubic centimeters of whole blood and (3) a red blood cell count of 5,000,000 or more cells per cubic millimeter.

Injection of plasma and whole blood should be regulated to keep the hemoglobin concentration in the patient's blood down to 15 Gm. per hundred cubic centimeters or the specific gravity of the whole blood down to 1.060.

Plasma protein concentration: The protein concentration in plasma can be quickly estimated from the specific gravity of the plasma as determined by the "copper sulfate method" from the formula $P = 360 (Gp - 1.007)$, where P is the plasma concentration in grams per hundred cubic centimeters and Gp the specific gravity of the plasma. The factor 1.007 is the correction needed for the nonprotein constituents of the plasma. If serum is used instead of plasma the loss of the fibrinogen results in values 0.2 Gm. per hundred cubic centimeters lower than the plasma values.

2 The normal plasma protein range is from 6.3 to 7.7 Gm. per hundred cubic centimeters with an average of 7 Gm. per hundred cubic centimeters, which latter value corresponds to a specific gravity of 1.0264. In burns a hyperproteinemia is not usual and is encountered only in the initial two to three hours and only in patients who have received no fluids and are dehydrated. A hypoproteinemia is the rule. The level may fall so low (below 5 Gm. per hundred cubic centimeters) that general edema results. If possible the protein concentration should not be allowed to drop below a level of 6.0 Gm. per hundred cubic centimeters (plasma specific gravity of 1.024).

1. Such oral therapy should be started immediately on admission before local treatment is begun and while waiting for parenteral therapy. However, in severe shock oral fluids should be started cautiously, as absorption may be slow and there is danger of vomiting and aspiration. In such cases, as already indicated, parenteral therapy must be begun at the earliest possible moment, while oral administration should not be pushed until the patient is out of shock.

2. If, after recovery from acute shock, the patient vomits, a quantity of physiologic electrolyte solution equal to the vomitus should be given again. If this happens repeatedly, oral fluid should be temporarily discontinued, but an attempt should be made to give electrolyte solutions again after a two to three hour rest period. In cases in which the stomach is loaded with food or lack of veins makes oral administration obligatory, preliminary washing out of the stomach to prevent aspiration of solid food, followed by Levine tube fluid administration by steady drip, may be advisable.

3. A definite schedule of oral fluid administration in terms of cubic centimeters per hour should be set up and closely followed to avoid overloading the stomach in an attempt to catch up, if enough fluid is not given in the first six hours. In severe burns, 200 to 400 cc. of fluid should be given regularly on the hour during the first eighteen to twenty-four hours. Usually very large volumes of fluid are tolerated in the first two days after injury. Contraindications are (*a*) the presence of thermal burns of the throat, larynx or lower air passages (a face burn should make one suspicious of such involvement), (*b*) presence of the casualty in a conflagration in an enclosed space where inhalation of toxic gases may have occurred and (*c*) in the aged or cardiac patient, when too vigorous fluid administration may increase the tendency to pulmonary edema. A reduced intake of electrolyte solutions and plasma and the substitution in part of whole blood is considered preferable therapy in such cases.

4. The urinary output is one important indication of the adequacy of fluid therapy. An attempt should be made to maintain the urinary output above 100 cc. per hour during the first forty-eight hours. Obviously at the beginning of treatment fluids administered will pass into dehydrated and injured tissues, and anuria for a matter of hours is not uncommon. With the schedule of treatment already described, however, urine output should start up at least after four or five hours and increase to the 100 cc. per hour level shortly thereafter. An inlying catheter may be useful to follow this more closely. It should be realized, however, that following shock, especially if prolonged, kidney damage may have occurred. If therapy as described does not open up the kidneys, excessive parenteral fluid, especially large quantities of intravenous saline solution, will not do so either but will only dilute blood and body fluids. A key measurement here is the plasma protein concentration, which should not be allowed to fall below 5.0 Gm. per hundred cubic centimeters (plasma specific gravity 1.021).

5. Treatment of Acidosis: If the severely burned patient has received no fluid therapy for several hours after the time of injury, acidosis is not infrequent; this is particularly likely if the patient has been in shock for any length of time. Acidosis should be promptly treated. Normally the carbon dioxide content of the plasma is about 60 volumes per cent.

For each volume per cent the plasma carbon dioxide is less than 55 volumes per cent in a 60 Kg. man give one of the following: (1) 40 cc. of 4 per cent sodium bicarbonate intravenously; (2) 125 cc. of 1.3 per cent (isotonic) (one-sixth molar) sodium bicarbonate orally or intravenously; (3) 125 cc. of 1.75 per cent (isotonic) (one-sixth molar) sodium lactate orally or intravenously; (4) 375 cc. of physiologic electrolyte solution (the larger dosage is necessary since, to prevent alkalosis when administered in large quantities, this solution is purposely made with only one-third the potential bicarbonate—and hence only one-third the antiacidotic power—as is contained in the one-sixth molar solutions).

Example: If the plasma carbon dioxide is 35 volumes per cent, 2,500 cc. of 1.3 per cent sodium bicarbonate should be given orally or intravenously. Such fluid should be given in place of rather than in addition to an equal volume of other fluid such as oral saline solution.

II. *Late Burns* (after forty-eight hours): *The Prevention and Treatment of Burn Toxemia, Anemia and Hypoproteinemia.*—Toxemia may be present early and cause fatalities as late as the third week. Anemia and hypoproteinemia may exist from the first few days and are troublesome until granulating surfaces are completely epithelized. Electrolytes as well as protein are lost from granulating surfaces and should be replaced by an adequate intake of salt in the diet.

Danger of giving too much fluid in later stages of burns: There is a strong tendency in both the edema absorption stage and in the toxemia infection stage for plasma and blood volume to increase above normal when excessive fluid is given, with cardiac strain, general edema formation, decreased renal function and pulmonary edema.

The chief aims of fluid treatment at this stage are as follows:

1. Maintenance of fluid balance and of normal electrolyte balance, a continuation of that listed in I. After forty-eight hours some resorption of the local edema may be expected and it may be unwise to force fluids and electrolyte as vigorously as during the period of local edema formation. If the therapy in the first forty-eight hours has been adequate, a normal intake of fluid with supplemental fluid and salt to cover continued loss from the wound should prove adequate.

2. Control of anemia.

3. Maintenance of body protein.

These aims are accomplished by the following means:

A. *Intravenous Therapy.*—1. Plasma or albumin is seldom necessary after the second day. A 500 cc. plasma transfusion usually contains less than 30 Gm. of plasma protein; a severely burned patient needs 150 to 200 Gm. of protein a day. Hence, while plasma transfusions are helpful in combating hypoproteinemia, they are quantitatively insufficient to accomplish much in this regard.

2. Amino acid solutions, as now available, can usually be tolerated intravenously in amounts up to 100 to 150 Gm. of amino acids in a 10 per cent solution if administered slowly. They are helpful during the first week or longer (after shock has been relieved) in sustaining and restoring the patient's state of nutrition but are indicated only if the patient cannot take adequate proteins by mouth.

3. Whole blood transfusions are of especial value at this stage. Most open burn surfaces are accompanied by a continued red cell loss (loss from bleeding, from increased red cell destruction due to infection and from failure of adequate red cell regeneration). Plasma protein is also lost from open burn surfaces in large

amounts. Whole blood in large amounts and at frequent intervals combats anemia and hypoproteinemia and is one of the best means of maintaining resistance to infection.

The following rules are of help:

(*a*) Give enough whole blood to raise the hemoglobin to 85 (hematocrit to 40, red count to 4.7 million) and to keep it above this level. As much as 1,500 cc. of whole blood daily for several days may be necessary to correct severe anemia in burns.

(*b*) Five hundred cc. of whole blood every three to four days as long as the rectal temperature is above 102 F. or the plasma proteins are below 6.0 Gm. per hundred cubic centimeters.

(For rules concerning Rh typing in repeated transfusions see I, A, 3.)

4. Electrolyte solutions by vein are seldom necessary in the later stages of burns because the patient usually can take sufficient fluids by mouth. However, when this is not possible, adequate fluid balance should be maintained by the use of intravenous physiologic electrolyte solution in sufficient but not excessive amounts. Glucose in saline solution may be substituted for the physiologic electrolyte solution, and at all times a high carbohydrate intake (100 to 200 Gm. a day) is advisable. In the late stages of burns, with infection and low plasma protein, urine volume may diminish, with edema of the body tissues. Strenuous forcing of electrolyte solution then may only increase edema, without diuresis. Moderate fluid intake, with feeding and whole blood transfusions, constitutes the logical treatment.

B. *Oral Therapy.*—The immensely important problem of feeding during the often protracted period of infection and anemia cannot be adequately covered in this memorandum. Each case is an individual problem of dietetics and nursing. A full food intake, including calories, vitamins and especially protein, is essential. A few notes may be useful:

1. Total fluid intake should be sufficient to keep the urine volume 1,500 cc. or higher daily. If salt intake has been adequate, body proteins not too much depleted and heart and kidney function competent, this usually means an intake of between 3,000 and 4,000 cc. daily.

2. Salt (sodium chloride) intake should be maintained around 10 Gm. daily; a little higher if the burn is extensive with much exudate. Too much salt, however, promotes general tissue edema. Blood carbon dioxide tends to run somewhat low, and some alkaline salt is advisable. Try to keep the urine about neutral to litmus. The physiologic electrolyte solution 1,000 to 1,500 cc. *daily will often be useful during the first five* to ten days. Water can be given ad libitum after the fourth day.

3. Diet should be high in protein, carbohydrate, calories and vitamins. The protein intake should be added to with increasing areas of third degree burns as early as possible after the injury and probably by the end of the first week. Such protein intake should be of the following magnitudes: 5 to 10 per cent body surface burned, 125 Gm. of protein per day; 10 to 20 per cent of body surface burned, 125 to 200 Gm. of protein per day; more than 20 per cent of body surface burned, more than 200 to 300 Gm. of protein per day, provided the patient's gastrointestinal tract can tolerate these large amounts. The corresponding caloric intake should be approximately 3,000, 4,000 or 5,000 calories per day.

(*a*) Amino acids by mouth, 100 to 200 Gm. per day, are an effective form of protein intake but difficult to tolerate because of the bad taste. Few patients can take them for more than three or four days.

(*b*) An example of an adequate diet is the diet used by Evans, which is palatable by mouth but also can be given by tube, as follows: 150 Gm. of dehydrated meat powder, 150 Gm. of powdered whole milk, 50 Gm. of corn oil, 150 Gm. of sucrose, 150 Gm. of dextrimaltose, 35 Gm. of chocolate and 1,000 cc. of water (plus vitamins, especially A, B, C and D, and iron).

(*c*) Adequate vitamins and iron are essential in all unhealed burns. A suggested daily dosage is as follows for burns of 20 per cent area of third degree. Correspondingly smaller doses should be used for less severe burns: vitamin A, 20,000 units; vitamin B: thiamine hydrochloride, 40 mg.; riboflavin, 20 mg.; niacin amide, 50 mg.; vitamin C, 1 Gm.; vitamin D, 2,000 units; vitamin K, 1 mg.; ferrous sulfate, 1.5 Gm.

ALCOHOL INJECTION OF LUMBAR SYMPATHETIC TRUNK

IN CASES OF PERIPHERAL VASCULAR INSUFFICIENCY WHEN SURGICAL SYMPATHECTOMY IS CONTRAINDICATED

GEORGE D. LILLY, M.D.
MIAMI, FLA.

The advantages of interrupting the sympathetic nerve supply to an extremity in which there is a circulatory deficiency due to vasospastic disease such as thromboangiitis obliterans or Raynaud's disease has been generally accepted, as a result of the pioneer work of Leriche [1] and the subsequent investigations of many American physicians.[2] The literature on this subject has been reviewed adequately at frequent intervals by White [3] and does not require general discussion at this time.

Unfortunately, some of the earlier publications dealing with peripheral vascular impairment of the extremities place too much emphasis on the differentiation between vasospastic disease and organic obliterative disease, and, as a result, many physicians regard the circulatory insufficiency of old age associated with arteriosclerosis as being an irreversible mechanical occlusion of the blood supply to the extremities. Ochsner and DeBakey [4] have emphasized the importance of realizing that even extreme cases of degenerative organic obliterative disease are aggravated by a certain amount of vasospasm and that the relief of this vasospasm is the one thing which can be accomplished by surgical treatment.

Read before the Section on Surgery, General and Abdominal, at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 14, 1944.

Recently Mahorner[5] reported good results following lumbar ganglionectomy in persons up to 60 years of age suffering from vascular insufficiency, and Trimble and his associates[6] have published the report of their gratifying experience in a large number of persons in their fifth and sixth decades who were relieved of their vascular insufficiency by lumbar sympathectomy.

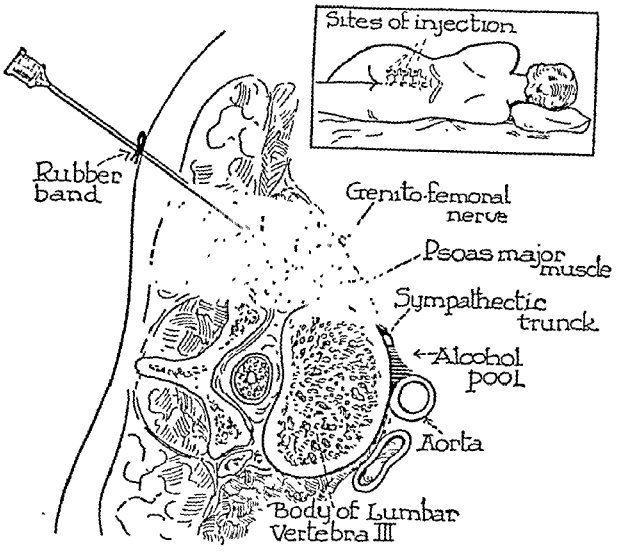

Fig. 1.—With the patient on the side the abdominal contents fall away from the vertebral column, creating a definite retroperitoneal space in the region of the sympathetic trunk. Gravity prevents the alcohol from coming in contact with the genitofemoral nerve.

My experience has coincided with that of Trimble, and we perform lumbar ganglionectomies on such patients when surgery can be tolerated with safety. A great many patients are seen, however, on whom surgery is definitely contraindicated because of heart disease, renal disease or both. In such cases I have resorted to a chemical sectioning of the sympathetic nerve supply to the lower extremities. This is accomplished by injecting sterile 95 per cent alcohol into the region of the lumbar sympathetic trunk. This procedure was undertaken with considerable misgiving because of the many reports of alcoholic neuritis following this type of injection. In some of my early cases alcoholic neuritis did develop but in the past three years I have encountered only 1 relatively mild neuritis of the genitofemoral nerve in a series of more than 150 cases. During this period it has been my practice to do an alcoholic injection of the lumbar sympathetic trunk on all patients suffering from arterial insufficiency of the lower extremities, regardless of their age or general physical condition, provided they were not considered good operative risks. Many patients with frankly infected gangrene have been injected, and it has been my impression that the procedure has enabled me to perform a satisfactory amputation at a lower level with better postoperative healing of the stump. I have had occasion to carry out the procedure on several aged patients, who were fibrillating and had developed saddle emboli of the lower abdominal aorta or of one of the femoral vessels. In these cases I have been able to relieve pain in almost every instance, and the improvement in circulation as a result of the interruption of the associated vasospasm of the collateral blood supply has been most striking. Very few of them have had to undergo amputation.

Many persons in their sixth, seventh and eighth decades have undergone bilateral alcoholic injection of the lumbar sympathetic trunks for relief of claudication and rest pain, and a majority of them have experienced relief from rest pain, much improved in claudication and a definite increase in their ability to walk. Most of those who had early pregangrenous areas on their great toes have overcome this tendency and have developed a healthier tissue in this region.

The following are presented as representative cases:

Case 1.—Mrs. W. H. P., aged 68, with hypertensive cardiovascular disease and severe generalized arteriosclerosis, suffered from rest pain in the calves for two years. Claudication had steadily increased and was so severe that she could not walk across her bedroom without resting. Two weeks prior to her first visit she developed trophic skin changes on the ends of the second and third toes of each foot. The only palpable pulse in the lower extremities was a very faint one at the femoral opening. Oscillometer readings were midcalf 0, midthigh ½ on both sides. During the past three days the patient had insisted on keeping her feet in a dependent position, and considerable edema developed. On Jan. 10, 1941 a bilateral alcohol injection of the first, second, third and fourth lumbar sympathetic ganglion was done. Following this injection the patient was relieved of her pain, and the gangrenous areas gradually healed, over a period of three weeks. Now, three and one-half years later, she is living and comfortable. There has been no recurrence of the gangrene or rest pain, and she can walk 100 feet without claudication.

Case 2.—O. S., a man aged 80 with hypertensive cardiovascular disease of fifteen years' duration with gradually increasing difficulty in walking, complained of cold feet, aches and cramps in the calf muscles during the night. All these symptoms were worse on the left side. For two weeks prior to admission a dark blue spot on the outer aspect of the left great toe became gradually larger, and for two days pus had been draining from it. Examination showed a fair pulse in both femoral vessels and a faint pulse in both popliteal vessels. There was no palpable dorsalis pedis or posterior tibial pulse. The feet were icy cold and white. There was an oscillometer reading of ½ in the midthigh. There was an infected gangrenous area of the skin on the great toe. On Dec. 16, 1942 a bilateral alcohol injection of the lumbar sympathetic trunk was done. The pain subsided immediately and the gangrenous areas cleared up promptly. The patient was last seen on Aug. 9, 1943, when he came in to advise that he was having no trouble and was walking 10 miles daily.

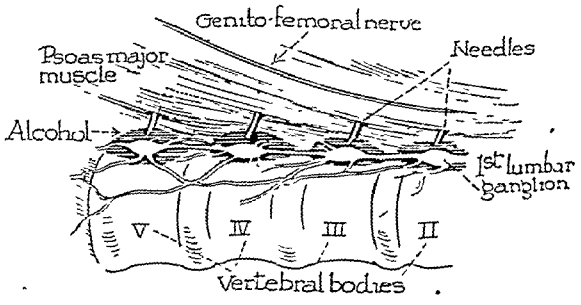

Fig. 2.—With the patient on the side the injected alcohol gravitates downward against the vertebral column and forms pools around the sympathetic trunk.

Case 3.—J. W. E., a man aged 67, presented a painful, cold, weak right lower extremity. He had been aware of a pulsating mass back of the right knee for several months. The day before admission, while lifting a heavy object, he experienced a severe pain back of the knee, followed by blanching and cooling of the leg and foot. The pain was unbearable, and he was unable to stand on the extremity. A diagnosis of

thrombosis of an aneurysm of the right popliteal artery was made, and an alcoholic injection of the right lumbar sympathetic trunk was done on Oct. 24, 1942. All pain was relieved and the temperature increased perceptibly. The next day the patient could walk on the extremity. On October 27 an obliterative endoaneurysmorrhaphy was done and the popliteal artery

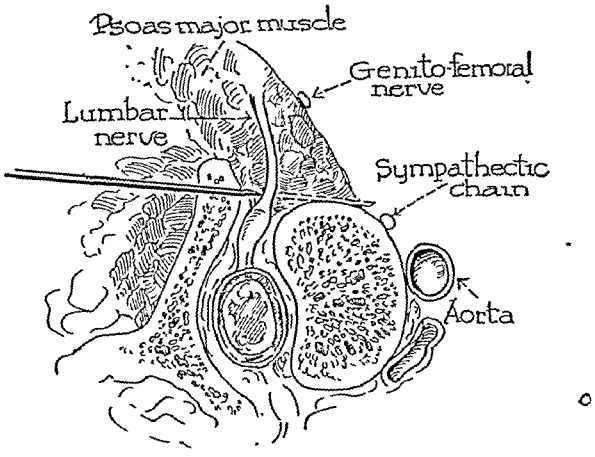

Fig. 3.—If the needle is not long enough, the alcohol may be injected into the substance of the psoas muscle and come into contact with the lumbar plexus. When the needle is inserted through the anterior surface of the psoas muscle, the muscle protects the lumbar nerves from the injected alcohol.

was ligated. The patient made an uneventful recovery and is now going about his usual activities. The right foot is warmer than the left one.

The technic that I employ for performing alcoholic injections is that which has been described by Ochsner and DeBakey[7] for infiltrating the same nerves with procaine, except that a few special precautions are taken in using alcohol which are not required in the use of procaine. As stated previously, the greatest hazard is associated with the danger of inadvertently allowing some of the injected alcohol to come in contact either with the genitofemoral nerve or with one or more of the lumbar nerve trunks (fig. 1). Damage to the genitofemoral nerve is avoided by placing the patient in a modified Sims position with the side to be injected turned up (fig. 2). In this position the injected alcohol pools against the side of the vertebral body and does not extend laterally over the anterior surface of the psoas muscle to come in contact with the nerve, which courses downward and laterally across the anterior surface of the muscle (fig. 3). The lumbar nerves emerge from the intervertebral foramens and pass into the substance of the psoas muscle. If the needle passes well through the substance of the muscle and into the retroperitoneal space, the danger of this complication is quite remote. The most frequent cause of trouble in this regard is the use of a short needle. The ordinary 2½ or 3 inch spinal needle is not long enough to reach the retroperitoneal space in a large, obese adult, and when such a needle is used there is danger of not penetrating the anterior surface of the psoas muscle. I use a special 22 gage 6 inch needle. This needle is inserted through a small piece of rubber band, which is used as a marker. When the tip of the needle strikes the posterior border of the transverse process I adjust the piece of rubber to a point 5 cm. from the skin surface and then insert the needle either above or below the transverse process until the rubber touches the skin. The needle is aspirated to make sure that the point has not been introduced into a blood vessel; then it is withdrawn about 0.25 cm. to avoid the possibility of injecting the solution into the wall of the aorta on the left or of the vena cava on the right. Not more than 2 cc. of 1 per cent procaine is injected slowly, the syringe is removed and a needle is inserted at the next level. Only 2 cc. of procaine is used because the creation of a pool of fluid at the end of the needle would dilute the alcohol which is subsequently injected and would possibly extend out over the psoas muscle to involve the genitofemoral nerve. By the time the second needle is put into position, adequate local anesthesia will have been obtained at the point of the first needle, and I then inject 2 cc. of sterile 95 per cent alcohol very slowly. About 0.25 cc. of procaine is then injected in order to clear the needle of alcohol and thereby avoid leaving any of the alcohol along the course of the needle as it is withdrawn. This injection is done at the level of the second, third, fourth and fifth spinous processes.

Following this procedure the patient is required to remain immobile for two hours to avoid any possibility of spreading the solution into an undesirable area. After two hours he is encouraged to resume his normal activities.

I determine the completeness of the sympathetic interruption by examining the extremity for moisture. If there is any perspiration on the involved extremity the procedure is repeated in two weeks.

It has been my experience that most of these injections are effective for at least six months and frequently for a year or more. One patient, who had a unilateral injection four years ago, still has a dry foot and leg on that side. I must have been fortunate enough in this case to effect an injection directly into the ganglions. I have encountered no contraindications to repeated injections, and reinjection is employed as often as it is indicated by the individual patient's clinical symptoms.

CONCLUSIONS

Paravertebral alcohol injection of the lumbar sympathetic ganglions is a relatively safe procedure when done carefully, and many inoperable persons suffering from arterial insufficiency of the lower extremities can be relieved by this relatively simple procedure. It is not advocated as a substitute for surgical sympathectomy but as a second choice when surgery is contraindicated.

ABSTRACT OF DISCUSSION

DR. ARTHUR W. ALLEN, Boston: Interruption of the sympathetic pathways to the extremities has a definite place in the treatment of certain peripheral lesions, particularly those that have to do with vasospasm. In the arteriosclerotic group, particularly, and in a great many cases of thromboangiitis obliterans this procedure does have definite merit. In testing these patients before operation by procaine block it takes much longer to get evidence of vasodilatation in obliterative disease than it does in the cases in which the vessels themselves are normal. Any clinic that has had a large experience in this field has tried the alcohol injections that Dr. Lilly has presented. Many of us have practically discarded the method on the basis of the neuritis so often associated with it. Any one who will take the trouble and pains to carry out Dr. Lilly's exact technic may get good results and not have the complicating sequelae which have troubled some of us so much. It has been interesting to watch these elderly patients after they have had surgical interruption of their sympathetic pathways. The mortality has been extremely low. The serious sequelae have been surprisingly few. Recently, however, a man came to our hospital with an arteriosclerotic popliteal aneurysm. He was subjected to lumbar ganglionectomy, and then by

7 Ochsner, Alton, and DeBakey, Michael: Therapy of Phlebothrombosis and Thrombophlebitis, Arch. Surg. 40:208 (Feb.) 1940

aneurysm was operated on and he was given heparin, as is the rule in our clinic following operations on the arteries. He developed a huge retroperitoneal hematoma, which contributed to his death. Possibly the heparin was started too soon. Perhaps it was unwise to use it in his particular case. However, if he could have had a chemical interruption of his sympathetics as described by Dr. Lilly, the probabilities are that he would be alive today. I wish to issue a slight warning about the wholesale and widespread sympathetic interruptions on arteriosclerotic obliterative disease in active persons who like to play eighteen holes of golf without having to rest on the fairways or who are troubled because they can walk only short distances at a time because of intermittent claudication. The operation is very popular at the moment and we may say to these patients "Why, yes, we can eliminate this cramp in your leg to a very large extent by doing this perfectly simple and safe operation of interrupting the lumbar sympathetic chain." These persons are spectacularly improved as far as the intermittent claudication is concerned. However, a certain number succumbed from coronary occlusion in an incredibly short period of months. It has led me to believe that perhaps if one is fortunate enough to develop arteriosclerosis that involves the lower extremities so that the chief handicap is that one must stop and rest while walking rather than stride forth as in previous years, it may be a protective mechanism of nature, and this should not be overlooked in dealing with this group of persons.

DR. GEORGE D. LILLY, Miami, Fla.: Three of my patients have developed coronary occlusion within a few months after satisfactory sympathetic block, although they had no coronary disease prior to the injection. It certainly seems reasonable to suppose that when they increase their activity they run some danger of precipitating a coronary occlusion. I do not feel that this complication is a contraindication to the procedure, especially if patients have severe pain or are threatened with gangrene; but I do believe it would be well to caution them against increasing their activity too much.

ANEMIA IN PREGNANCY

A CORRELATION OF THE PERIPHERAL BLOOD AND BONE MARROW FINDINGS

JOHN R. WOLFF, M.D.
AND
LOUIS R. LIMARZI, M.D.
CHICAGO

Since the circulating blood is affected by many physiologic processes (e. g. work, rest, food, exercise, emotion, infection), an analysis of the peripheral blood by capillary or vein puncture merely tells the state of the blood at the moment it is obtained. The bone marrow is more constant in its pattern and portrays both the present state of the blood organs and the immediate future of the peripheral blood. The correlation of these findings in both the bone marrow and the circulatory blood reveals the true state of the hemopoietic system.

As clinicians, we have difficulty in evaluating the blood findings commonly seen during pregnancy. Because the hemoglobin and erythrocyte values are lower than those seen in the nonpregnant individual, earlier workers thought that pregnancy produced a true anemia. They speculated that this was an iron deficiency anemia due to the demands of the fetus for iron from the mother.

From the Department of Obstetrics and Gynecology and the Department of Medicine, University of Illinois College of Medicine.

Read before the Section on Obstetrics and Gynecology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 14, 1944.

Owing to lack of space this article is abbreviated in THE JOURNAL. The complete article, including additional material, tables and photomicrographs, will appear in the authors' reprints.

Dieckmann and Wegner [1] found that the total blood volume was increased 23 per cent during pregnancy and that, although this increase is proportionately greater in the plasma content, the cellular content is also increased. They reported an increase in the total circulating hemoglobin and erythrocytes. However, the plasma is so greatly increased that when a small sample of blood is analyzed the cellular element is diluted. The apparent anemia previously observed is therefore not a true anemia but rather a physiologic anemia or hydremia. This work has been amply confirmed by other workers.[2] Adair and Dieckmann [3] state that the minimum normal figures during pregnancy are hemoglobin 10 Gm., erythrocytes 3.36 million and cell volume 33 per cent.

There are some investigators who do not believe that hydremia alone can produce figures as low as those just mentioned. Whitby [4] says that an erythrocyte count below 4.0 is pathologic. Bethell [5] states that 3.70 million red cells and 11.3 Gm. of hemoglobin are the lowest that will explain a hydremia.

Many clinicians believe that the lowered values seen in pregnancy are due to a lack of iron.[6] This lack is thought to be due either to a withdrawal of the mother's iron reserve for the fetus, to the lack of iron in the diet or to the prevention of its absorption by the change in the gastric secretion during pregnancy.[7] Many clinicians have routinely treated pregnant women with iron in one of various forms and have noted higher erythrocyte and hemoglobin levels in those treated than in control cases.[6] Yet others [8] have found that iron did not affect these values at all.

RESULTS

Physiologic Anemia of Pregnancy.—Thirty patients were examined throughout pregnancy. These normal healthy pregnant women were first seen during the first six to ten weeks of pregnancy. At this time the peripheral blood and bone marrow were examined as described. The peripheral blood was reexamined every four weeks until delivery, shortly after delivery and at the six weeks postpartum visit. The bone marrow was reexamined in many cases during the second and third trimester, in all cases shortly after delivery and in most cases at the final six weeks postpartum visit.

Peripheral blood and bone marrow analysis were also made on 75 other healthy women at various stages of their pregnancy.

The findings in the peripheral blood are in agreement with those of previous investigators (table 1). There is a lowering of the values of hemoglobin, erythrocytes

Fig 1.—Normal pregnancy: peripheral blood, showing the normocytic normochromic anemia

and hematocrit beginning in the third and fourth months of pregnancy. This is much increased by the sixth and seventh month and persists in our series until after delivery. By the sixth postpartum week the blood has returned to normal levels. We note that the mean corpuscular volume is normal throughout pregnancy. In a few cases the volume of the cell on one or two examinations would be small and in other cases somewhat macrocytic, but the average cell throughout pregnancy was normal in size and volume. The mean corpuscular hemoglobin concentration is in the lower limits of normal. Since 32 to 36 per cent is considered the range of normal hemoglobin concentration it would be difficult to state that the erythrocytes are deficient in iron during pregnancy. The larger group of individual cases examined at various months of pregnancy reveal findings similar to those as observed in the same patients (30) throughout pregnancy. The leukocytes were usually within the normal range, but many patients showed a slight leukocytosis at varying times during the pregnancy. The latter fact has been previously noted by Litzenberg and others.[11] We also found an increase in the sedimentation rate, especially in the last trimester, with a rapid return to normal following delivery. The icterus index remained normal throughout pregnancy. In contrast with observations of other investigators,[12] we failed to note an increase in the reticulocytes during pregnancy. The differential smear showed little variation from normal. The erythrocytes always appeared normal in size and shape and in staining quality throughout the pregnancy. In most cases the percentage of polymorphonuclear leukocytes was increased toward the end of pregnancy and there was slight increase in stab forms noted in many instances. The leukocytosis of labor (polymorphonuclear in type) was evidenced by a mild leukocytosis noted during the puerperium. The leukocytes were normal at the sixth postpartum period. The blood platelets are normal or slightly increased.

The bone marrow of normal pregnancy shows no change in the character of normal erythropoiesis. The characteristic cell is that of the polychromatophilic *normoblast. The latter type of the erythroid element* is exactly like that seen in normal healthy nonpregnant women. There is definite evidence of increased myelopoiesis during the first and second trimesters. During the latter part of pregnancy, especially in the last month of gestation and during the puerperium, there is a pronounced myeloid hyperplasia with a tendency toward granulopoietic immaturity. The megakaryocytes are normal or slightly increased in number during the early months of pregnancy, but during the latter months of

Fig 2.—Normal pregnancy: bone marrow, showing normal erythropoiesis and myeloid hyperplasia

pregnancy and especially in the early puerperium there is an evident megakaryocytic hyperplasia of a mature type. There is also a decided increase in the number of bone marrow platelets. This myeloid hyperplasia and megakaryocytic hyperplasia does not entirely return

to normal until some three months following delivery despite the relative earlier readjustment of the peripheral blood.

Iron Deficiency Anemia (table 2).—Ten cases were observed. Table 2 shows the average findings in this group. The essential feature is a cell deficient in

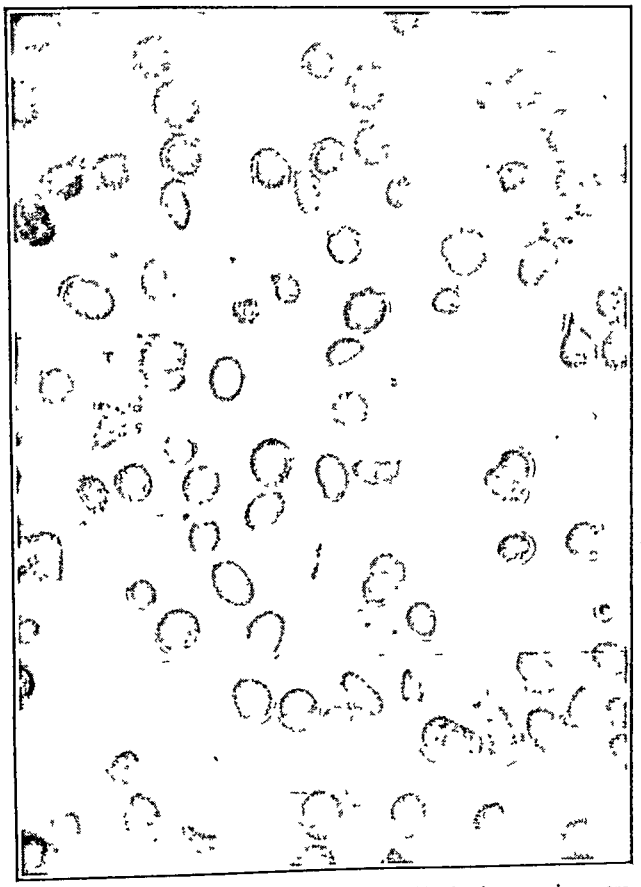

Fig. 4.—Iron deficiency anemia peripheral blood, showing the microcytic hypochromic anemia

hemoglobin, the so-called hypochromic anemia. The hemoglobin falls well below 10 Gm. and the erythrocyte count and hematocrit reading are below those applicable to that of the physiologic changes seen in pregnancy. Calculation of the mean corpuscular hemoglobin concentration shows a decided lack of hemoglobin in the cell. In 4 cases the cell volume was normal, a normocytic hypochromic anemia and in 6 cases the cell volume was considerably lowered, a microcytic hypochromic anemia.

The bone marrow shows a normoblastic erythropoiesis with the presence of a greater or smaller number of pronormoblasts and basophilic normoblasts, but of a normal type. In 1 case with a severe anemia the erythroid hyperplasia in the bone marrow showed an exceedingly large number of pronormoblasts. The pronormoblasts and basophilic normoblasts are only infrequently encountered in bone marrow smears of normal patients and those with the physiologic changes due to pregnancy. A myeloid hyperplasia and megakaryocytic increase is noted in these cases similarly to that described.

When iron was not given to these patients (6) the peripheral blood and bone marrow remained constant as described. When iron was given to these patients (4) the peripheral blood and bone marrow returned to normal. Without iron the bone marrow does not return to normal until six months after delivery.

Four cases of mild anemia (hemoglobin below 10 Gm. and erythrocytes below 3.50 million) were observed in which the cell size was small but the hemoglobin concentration was normal. The bone marrow showed a normal erythroid pattern.

Macrocytic Anemia of Pregnancy (table 3).—Three cases of anemia of pregnancy and the puerperium were observed with a megaloblastic bone marrow quite identical with that seen in addisonian pernicious anemia.

In the first case it was the ninth month of pregnancy. The peripheral blood showed 4 Gm. of hemoglobin, 1.15 million erythrocytes and a hematocrit of 13 per cent. The mean corpuscular volume of 113 cubic microns revealed the macrocytic type of cell. The hemoglobin concentration was 30 per cent. The blood smear revealed moderate anisocytosis and poikilocytosis of the erythrocytes and moderate polychromasia. So-called pernicious anemia neutrophils were also present. There was an abundance of hydrochloric acid in the stomach contents following an alcohol meal or following the injection of histamine hydrochloride subcutaneously. The smooth tongue, splenomegaly and neurologic complications characteristic of true pernicious anemia were not observed.

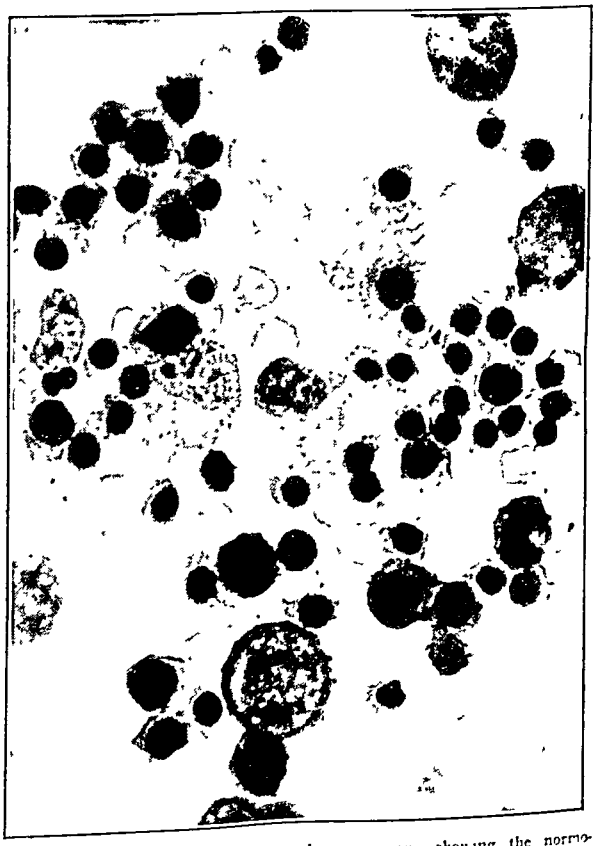

Fig. 5.—Iron deficiency anemia bone marrow, showing the normoblastic hyperplasia

The bone marrow was characterized by the presence of megaloblasts. This is a pathologic type of erythropoiesis which occurs in the bone marrow only in pernicious anemia and related anemias due to a deficiency of the liver principle. This type of marrow is never seen under normal conditions. Megaloblasts are distinctly different from the early forms of normoblasts

(pronormoblasts) and are characterized by a more distinct chromatin network, more parachromatin, more rapid accumulation of hemoglobin in proportion to the maturity of the cell and almost always by a larger cell. Jones [13] has discussed in detail the distinguishing features of both normoblasts and megaloblasts in relation

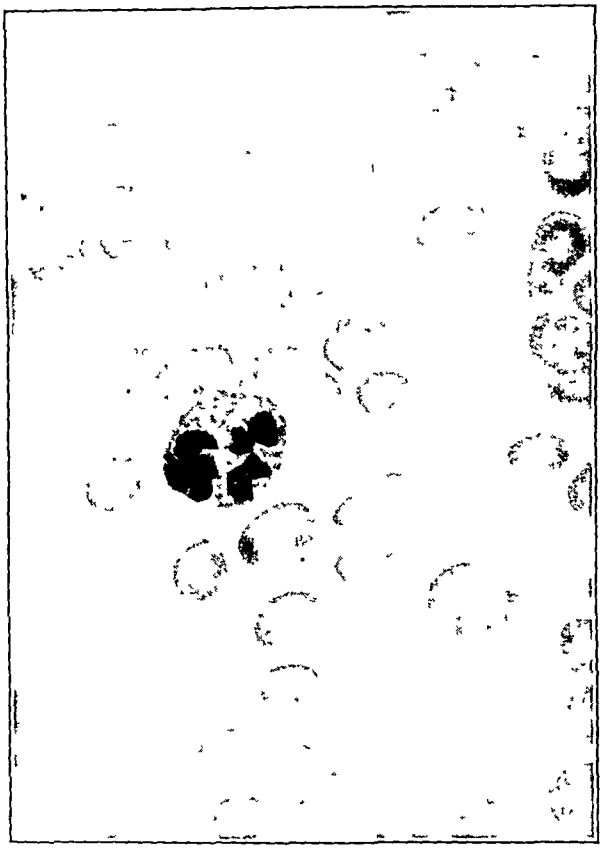

Fig 8.—Pernicious anemia of pregnancy; peripheral blood, showing a pernicious anemia neutrophil (macropolycyte)

to their nuclear pattern and cytoplasmic changes. Limarzi [14] has demonstrated that megaloblasts are arsenic sensitive, while pronormoblasts as seen in normal bone marrow and in the bone marrow in most cases of anemia with an erythroid immaturity are arsenic resistant. The bone marrow in those cases of so-called pernicious anemia of pregnancy also present a pathologic type of granulopoiesis characterized by large hyperpolymorphic neutrophilic promyelocytes, myelocytes and metamyelocytes. These types develop in the pernicious anemia neutrophils (macropolycytes) of the peripheral blood

In the second case the peripheral blood showed the hemoglobin to be 4.5 Gm., red cell count 1.27 million and the hematocrit 12 per cent. Thus the mean corpuscular volume is 94 cubic microns, which is well within normal limits. The mean corpuscular hemoglobin concentration is 35 per cent. One would classify this as a normocytic normochromic anemia, and the etiology and therapy would be somewhat obscure. However, the bone marrow findings were those of a typical megaloblastic anemia as already described.

In the third case the peripheral blood showed the hemoglobin 5.5 Gm., erythrocytes 2.48 million and hematocrit 19 per cent. The mean corpuscular volume was 76 cubic microns and the mean corpuscular hemoglobin concentration was 28 per cent. From the study of the peripheral blood alone one would classify this case as a microcytic hypochromic anemia. That is, it would be considered an iron deficiency anemia and treated accordingly. However, the bone marrow again revealed a true megaloblastic anemia typical of the cases just described.

Intramuscular liver therapy is needed in these cases with a megaloblastic marrow. Following this treatment there is a tremendous proliferation of normoblasts in the bone marrow. Megaloblasts rapidly mature and no new megaloblasts are formed. The action of the liver principle on the megaloblasts is probably to effect the elimination and suppression of their further proliferation.[15] It is not clear how liver extract effects stimulation of the normoblastic tissue. Apparently once the pathologic megaloblastic tissue has been eliminated and suppressed, normoblastic erythropoiesis can assume its normal physiologic function and the anemia in the peripheral blood is corrected. In cases of megaloblastic anemia (pernicious) of pregnancy the conversion of the bone marrow from a megaloblastic to a normoblastic type of erythropoiesis following liver therapy is slow. These cases do not respond as well as

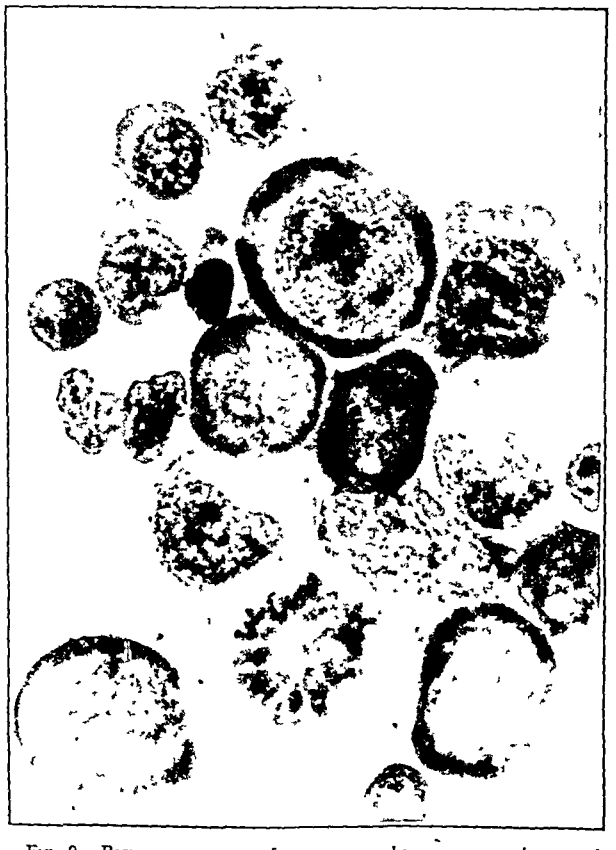

Fig 9.—Pernicious anemia of pregnancy; bone marrow, showing the megaloblastic type of erythropoiesis and abnormal granulopoiesis. Note the presence of a mitotic figure in one megaloblast

cases of addisonian pernicious anemia until after the birth of the child and for some time after the puerperium.

It requires large daily doses of potent intramuscular liver extract and several blood transfusions to bring about a satisfactory recovery phase. The reticulocyte response is never as high as that seen in addisonian pernicious anemia at the equivalent stage of blood and bone marrow findings. In 1 case the pathologic granulopoiesis disappeared more rapidly than the megaloblastic erythropoiesis, while in the other 2 the granulopoiesis was last to disappear, similar to that seen in addisonian anemia. The megakaryocytes were hypoplastic before treatment but increased with treatment.

Fig. 10.—Pernicious anemia of pregnancy: bone marrow, showing the conversion to normal erythropoiesis following liver therapy. Note the large pathologic neutrophilic metamyelocyte.

The peripheral blood and bone marrow recover completely and permanently in about five months after delivery. The infants show normal blood and bone marrow findings, as do other children of the mother.

Six cases of mild anemia in which the mean corpuscular volume revealed a macrocytic type of cell were observed. The mean corpuscular hemoglobin was either normal or slightly below normal. The bone marrow was normal in all respects except for a mild myeloid hyperplasia. In some instances there was a mild erythropoiesis with the presence of a few immature forms (pronormoblasts), but megaloblasts were never found. In these cases recovery followed delivery, although iron was given in those in which there was a lowered hemoglobin concentration.

PHYSIOLOGIC ANEMIA

The bone marrow of normal pregnancy has been studied by several investigators. Daniachij [16] examined the sternal marrow of 50 women during different stages of pregnancy and the puerperium. He found an increase in the number of neutrophilic metamyelocytes and a megaloblastic type of reaction which reached its maximum between the seventh and eighth months of pregnancy. Forssell [17a] examined 8 cases during the first month of pregnancy and noted no difference in the differential counts between pregnant and normal nonpregnant women. Hansen [17b] noted signs of increased erythropoiesis indicated by the finding of normoblast clusters in nests. No statement is made as to the number of cases studied. Markoff [18] reported morphologic studies on the bone marrow in pregnancy. No indication is given as to the total number of cases in which these observations were made. He found an increase in erythropoiesis with normoblasts in nests and an increase in the number of macroblasts from the second to the sixth months of pregnancy. A tendency to large cellular forms in both the myeloid and the erythroid series was found to be present. An increase in eosinophilic cells and a plasma cellular reaction was also noted. Pitts and Packham [13] examined the bone marrow from 41 women in various stages of pregnancy and compared the total number of marrow cells and differential counts with that of 20 nonpregnant women as controls. They found a slight but significant higher count during pregnancy (14,400 to 125,000 per cubic millimeter, average 36,760) to that of the control cases (7,550 to 46,000, average 23,100). These counts are low because these authors aspirated 10 cc. of marrow fluid and this leads to dilution with sinusoidal (peripheral) blood. They found similar differential counts in both pregnant and nonpregnant women.

In our series of 105 normal healthy pregnant women, 30 of whom were studied throughout pregnancy, the bone marrow constantly revealed a normal pattern of erythropoiesis. This is further evidence that the normocytic anemia in the peripheral blood is not a true one but due to hydremia. In fact we must agree with those who prefer dropping the status of "anemia" from these patients and in its place instituting normal standards of the blood during pregnancy which will naturally differ from the accepted nonpregnant standards. According to Adair [3] 89 per cent of all pregnant women are in this group. No treatment of any type is necessary. Iron medication is of no value, as the cells are well concentrated with iron. Studies of the iron content of the blood show normal findings during pregnancy.[19] The bone marrow, as stated, shows evidence of an entirely normal erythropoiesis.

An increased myelopoiesis was observed early in pregnancy. This became more pronounced during the last months of pregnancy. This hyperplasia is reflected in two ways: 1. By a pronounced bone marrow cell

volume in the hematocrit. The normal myeloid-erythroid volume is approximately 6.8 per cent. The average during pregnancy was 14 per cent, with values as high as 45 per cent noted. 2. By an increase in the number of nucleated bone marrow cells. Normally the bone marrow of an adult woman contains approximately 300,000 cells per cubic millimeter,[20] while during pregnancy the average is about 600,000 per cubic millimeter with figures as high as 1.0 million often noted. Apparently homoplastic myelopoiesis is accelerated and the insignificant myeloid immaturity observed near the end of pregnancy does not involve the mechanism of heteroplastic myelopoiesis. The slight to moderate leukocytosis observed in the peripheral blood is practically always of the polymorphonuclear neutrophilic type and rarely if ever shows signs of myeloid immaturity.

The megakaryocytic hyperplasia of the bone marrow is only occasionally reflected in the peripheral blood by a great increase in the number of platelets. The mechanism for the rapid and immediate formation of large quantities of platelets is present in the bone marrow, especially during the last months of pregnancy and the puerperium. The relationship of megakaryocytic hyperplasia with the formation of large numbers of blood platelets to the control of postpartum bleeding, the tendency to phlebitis in the puerperium and the increased blood coagulability noted in those with an eclamptogenic toxemia is an interesting speculation.

These hyperplastic changes in the bone marrow and peripheral blood during pregnancy are merely a part of similar physiologic changes noted in every other organ of the body during pregnancy. The bone marrow does not return to normal for at least six weeks after delivery. It thus takes longer to recover than does the peripheral blood and is therefore a finer indicator of complete physiologic adjustment following pregnancy than are the blood or physical findings in this respect. The baby born of the mother shows normal blood and bone marrow findings.

IRON DEFICIENCY ANEMIA

In the cases of hypochromic anemia, especially with a microcytic cell, the bone marrow shows a definite normoblastic hyperplasia with a moderate to pronounced erythroid immaturity to include many more basophilic normoblasts and pronormoblasts than are seen in normal bone marrows. Markoff [18] in cases of microcytic anemia observed a normoblastic erythropoiesis with frequent macronormoblasts. Segerdahl [21] observed a similar type of marrow in her cases of pregnancy with an iron deficiency anemia (sideropenia). The factors that contribute to this type of anemia are similar to those contributing to this state in nonpregnant individuals. That is, the chronic loss of blood (e. g. epistaxis, menorrhagia, hemorrhoids, ulcer) preceding the pregnancy, the lowering of the gastric acidity during pregnancy and dietary alterations alone or in combination tend to produce this anemia. Following the replacement of iron therapeutically, an adequate diet and in some cases diluted hydrochloric acid the bone marrow returns to normal and the anemia in the peripheral blood is corrected. It is interesting that the babies from these mothers show normal peripheral blood and bone marrow findings.

In all cases of evident true anemia or those falling at or just below the level of minimum standard during pregnancy, the key to iron therapy is the mean corpuscular hemoglobin concentration. Every such case deserves a complete investigation of the peripheral blood. The simple hematocrit reading should always be obtained along with the erythrocyte count and the hemoglobin level. The mean corpuscular hemoglobin concentration can then be established. When this index is below normal, iron is indicated. We believe that ferrous sulfate 15 grains (1 Gm.) daily is the best preparation.

MEGALOBLASTIC ANEMIA OR PERNICIOUS ANEMIA OF PREGNANCY

True addisonian pernicious anemia is rare during pregnancy, although many of Biermer's patients were pregnant women. Much of the older reports of pernicious anemia in pregnancy are incomplete not only because of the lack of present rigid diagnostic criteria, especially bone marrow studies, but because any grave or severe anemia was called pernicious. Thus many of the older reports must be looked on with great suspicion. Much of the literature on the blood in the macrocytic anemias of pregnancy has been reviewed by Sodeman.[23] Bone marrow examinations are lacking in practically all of these cases of macrocytic anemia reviewed by him.

In our 3 cases of pernicious anemia of pregnancy megaloblasts were observed in all the bone marrows. Our patients were all white women in the ninth month of pregnancy. Besides the megaloblasts the bone marrow revealed a pathologic type of granulopoiesis. This is characterized by large hyperpolymorphic neutrophilic promyelocytes, myelocytes and metamyelocytes as described by *Jones* [30] *in typical cases of pernicious anemia.* These cells develop into the pernicious anemia neutrophils (Cook's [31] macropolycytes) of the peripheral blood.

The finding of a megaloblastic bone marrow in the presence of either a macrocytic, a normocytic or a microcytic peripheral blood is most interesting. Segerdahl,[32] Lambin and de Weerdt,[32] Callender [29] and Davidson, Davis and Innes [33] have reported similar types of cases. The latter investigators have suggested the name "megaloblastic anemia of pregnancy." The clinical importance of the analysis of the bone marrow as obtained by sternal puncture in all cases of severe anemia during pregnancy is obvious. Also in such severe anemias one may be misled by the findings in the peripheral blood from discrepancies produced by invariable technical errors, whereas the sternal marrow analysis is simple and devoid of such a happening. Our patients with megaloblastic anemia responded to adequate liver therapy and blood transfusions.

SUMMARY

The normal status of erythropoiesis in the bone marrow shows that the physiologic anemia of pregnancy is not a true anemia and thus rules out the need of routine therapy. The cause of the pronounced myeloid and megakaryocytic hyperplasia is not entirely clear. It

may be that the granulocytic cells in the living state or their products act as a productive mechanism during pregnancy and the puerperium. The findings of a polymorphonuclear leukocytosis and thrombocytosis during the latter part of pregnancy, labor and the puerperium can be definitely correlated to the findings in the marrow. It is interesting to note that the bone marrow is apparently the last organ to return to a normal state following delivery.

In the hypochromic anemia of pregnancy the conspicuous finding of a disturbance in the erythroid tissue in the form of normoblastic hyperplasia and immaturity but morphologically normal cells speaks for an iron deficiency anemia. The microcytic hypochromic anemia will respond to therapeutic doses of iron. In cases of microcytic normochromic anemia (small cell with normal hemoglobin saturation) and a normal bone marrow iron therapy is of little value. Following delivery the anemia will correct itself spontaneously.

The macrocytic anemia with a normal or pronormoblastic bone marrow will in most instances clear up spontaneously during the puerperium. A normal hemoglobin concentration contraindicates the use of iron, but when this index is low iron should be administered. The absence of megaloblasts rules out pernicious anemia of pregnancy, and liver is not indicated.

In the pernicious anemia of pregnancy with megaloblastic bone marrow and a macrocytic anemia in the peripheral blood, the diagnosis is obvious and the treatment is clear. Large doses of intramuscular liver extract and supportive blood transfusions will carry the patient through the pregnancy and the puerperium. Unless the megaloblasts have been purged from the bone marrow by liver extract, the anemia in the peripheral blood will not be corrected. These cases are refractory to iron medication. Following delivery recovery is apparently complete and permanent, although these women should be observed during future pregnancies and following the menopause for the development of true pernicious anemia. The findings of a normocytic or microcytic and hypochromic anemia may be misleading unless the bone marrow is examined and the presence of megaloblasts observed. It can be said that hypochromic anemia with a normoblastic bone marrow will respond to iron and that a hypochromic anemia with a megaloblastic bone marrow will respond only to anti-pernicious anemia therapy. The fact that these cases respond to liver therapy emphasizes the need for recognizing genuine megaloblasts in the bone marrow in order to determine the correct type of therapy. Perhaps the unexplained success that some clinicians have reported in the treatment of hypochromic anemia with liver extract has been due to the existence of a condition like this. The presence of pernicious anemia neutrophils in the peripheral blood smear prior to the development of a macrocytic blood picture emphasizes the importance of a careful qualitative study of cellular morphology. The presence of these atypical neutrophils in the blood aids in differentiating pernicious anemia of pregnancy from microcytic or normocytic types of hypochromic anemia.

CONCLUSIONS

Four types of bone marrow and peripheral blood patterns are observed during pregnancy:

1. A normocytic normochromic anemia in the peripheral blood. The bone marrow shows a normal erythroid pattern with a myeloid and megakaryocytic hyperplasia toward the end of pregnancy. The physiologic anemia is a normal state during pregnancy and is due to hydremia. Recovery is spontaneous during the puerperium. No therapy is needed.

2. A microcytic hypochromic anemia with a normoblastic hyperplasia in the bone marrow. Adequate iron therapy corrects the bone marrow and the anemia. Occasionally a mild microcytic normochromic anemia with a normal or normoblastic bone marrow is observed. No treatment is necessary as recovery follows delivery.

3. A macrocytic anemia with a normal or pronormoblastic bone marrow. Recovery follows delivery. Iron is indicated only when the mean corpuscular hemoglobin concentration is low.

4. A megaloblastic type of bone marrow with either a macrocytic, normocytic or microcytic and hypochromic peripheral blood pattern. Adequate liver therapy and supportive blood transfusions are needed to carry the patient through the pregnancy. Complete and permanent recovery usually follows. Atypical neutrophils (macropolycytes) in the peripheral blood are a diagnostic aid.

The most accurate criteria for the diagnosis and treatment of the true anemia of pregnancy is the study of the sternal marrow. The changes in the peripheral blood are of a secondary nature and in many instances are misleading.

The close cooperation of the hematologist and obstetrician is essential to the proper management of the anemic state seen during pregnancy.

1853 West Polk Street, Chicago 12.

ABSTRACT OF DISCUSSION

DR. WILLIAM J. DIECKMANN, Chicago: Our trained technicians working with 75 to 150 patients a day, using the Newcomer method, had an error in the hemoglobin determination of 8.7 per cent. With special care this error was 4 per cent. The routine erythrocyte count had an error of 13.7 per cent, while with special care the error was 2 per cent, but the hematocrit, using heparin, had an error of only 2 per cent. Furthermore, the hemoglobin concentration in the same individual, with careful determinations, can fluctuate as much as 15 per cent from hour to hour. More than one hemoglobin determination must be made to establish a diagnosis of anemia or of normality for the patient. The paper contains no data as to how quickly the patient's hemoglobin improves during pregnancy with either liver injections or iron. Our experience at the Chicago Lying-In Hospital, where we have over 2,000 clinic visits monthly, is that 63 per cent are anemic as judged by the standards for the nonpregnant (that is less than 12 Gm. of hemoglobin, 36 hematocrit or 4,200,000 red blood count) or 12 per cent are anemic as judged by the standards for pregnancy (that is less than 10 Gm. of hemoglobin, 33 per cent hematocrit or 3.36 million erythrocytes). We have been giving both ferrous and ferric iron and various proprietary preparations of iron containing liver, stomach and vitamin extracts. Any medication must show a higher percentage of cure and a more rapid return to the normal than our group of controls. We are still using various combinations of iron and other substances in an endeavor to find some substance that will cause improvement of anemia in pregnancy. After delivery or in the nonpregnant woman an adequate iron intake in an iron deficient anemia will cause an appreciable increase in hemoglobin within two weeks. We have seen no such increases in anemic pregnant women. Antepartum care is valuable, but a hemoglobin determination made in the last month is of more value than one made in the third month,

and for the past year we have been insisting on a hemoglobin determination within the month preceding delivery. It is hard for me to believe that the fetal needs for iron are the cause for the anemia of pregnancy and that the pregnant woman must have an increased intake of iron prior to twenty-eight weeks. The incidence of anemia was much higher in our ward patients than in our private patients, and my impression is that in the past few years the incidence has decreased in the ward patients. Patients who are found to have a hemoglobin of less than 10 Gm. per hundred cubic centimeters at delivery are watched carefully to prevent excessive blood loss and the preliminary preparations for transfusion made. If the hemoglobin is less than 9, the patients are transfused either before or directly after delivery. Transfusion entails a risk from incompatible blood, which has become a real one since the war because of the inexperience of the resident staff. Nevertheless, transfusions are carried out because the anemic patient is particularly susceptible to puerperal infection.

DR. HOWARD L. ALT, Chicago: These interesting observations of Dr. Wolff and Dr. Limarzi show that the peripheral blood is not always an index of the bone marrow pattern. I don't think the day is far off when the sternal marrow differential will be almost as routine a procedure as the peripheral blood differential is today. In interpreting the blood count in pregnancy, it is of utmost importance to define the limits of normal. The most common so-called anemia of pregnancy which I see is in the woman in the sixth to eighth month who has a red count in the neighborhood of 3.3 million and hemoglobin of 10 Gm. According to most standards, this degree of depression should not be called anemia; it represents the lower limits of normal. Such patients frequently have low normal counts, i. e. a red blood cell count of about 4.0 million and hemoglobin of 12 Gm. for years preceding the pregnancy. The iron deficiency anemia seen during pregnancy practically always antedates the period of gestation. We know that iron deficiency is common in women during the childbearing period. A hemoglobin of 11.0 Gm. might be disregarded before pregnancy, but, as the hydremia of pregnancy progresses, further lowering of the hemoglobin attracts the attention of the obstetrician and the case is then diagnosed as an iron deficiency anemia. The amount of iron stored in the fetus, placenta and uterus is not sufficient to produce a real iron deficiency anemia if the woman had a normal reserve before she became pregnant. The megaloblastic anemia of pregnancy described is obviously not a true addisonian anemia. The patients had free hydrochloric acid, and 2 did not have macrocytosis. Further, they had a normal icterus index and did not respond in the usual manner to liver extract. I wonder if there is a relationship between this syndrome and so-called primary refractory anemia or achrestic anemia that has been described in the literature. I have seen 1 such instance in a male with a megaloblastic marrow and a hypochromic anemia in the peripheral blood. Further studies of this interesting syndrome occurring during pregnancy are warranted. Of course, besides these three anemias of pregnancy one should also think of the anemias that occur in nonpregnant women. About six weeks ago I saw a woman four and a half months pregnant with a red blood cell count of 1.5 millions. Complete studies revealed the presence of a subacute leukemia. She died four weeks later. If she had lived another six weeks or so it might have been possible to obtain a live infant.

DR. FRANK H. BETHELL, Ann Arbor, Mich.: There are two or three points that I should like to make in connection with this hematologic study by Drs. Wolff and Limarzi. What is the true incidence of anemia in pregnancy? I do not believe that a definite statement can be made because the incidence and severity of anemia in pregnancy varies with the group of patients under observation, depending on economic status, type of antepartum care and a number of other factors. In a group of 484 women in modest economic circumstances whom my associates and I studied at monthly intervals during pregnancy and for a year after delivery we found an incidence of true anemia of 28 per cent, and of those about four fifths were of the hypochromic type. As far as the etiology of these anemias is concerned, I do not share the view that the subject is entirely obscure. I think that iron deficiency in pregnancy can readily be explained. It is largely accounted for by preexisting depletion of iron in young women due either to repeated pregnancies or to hypermenorrhea, or to dietary deficiency. In our subjects, who were studied carefully from the point of view of diet, we found that if the daily food iron habitually taken before pregnancy and during the early months of pregnancy exceeded 15 mg. there was no incidence of hypochromic anemia, but the diet of only about 10 per cent of the group insured that amount of iron intake. On the other hand, about a third of the subjects were habitually receiving less than 8 mg. of iron a day, and of these 36 per cent had hypochromic anemia. My associates and I have previously demonstrated that the protein content of the diet bears an important relationship to the incidence of anemia in pregnancy, particularly of the normocytic and macrocytic types. We have evidence indicating that dietary deficiencies are responsible for the majority of the common anemias in pregnancy and that dietary control is an essential part of adequate antepartum management.

DR. LOUIS R. LIMARZI, Chicago: A great deal of the discussion concerning the anemias of pregnancy is due to poor or incomplete studies of the peripheral blood. One should be cautious in calling an anemia normocytic, microcytic or macrocytic on the basis of a hemoglobin determination and erythrocyte count alone and without the determination of the volume of packed red cells (hematocrit). From a physiologic and therapeutic point of view the accurate method of determining the type of anemia during pregnancy is from a study of the bone marrow by sternal aspiration. This is a simple and practical procedure. In the physiologic normocytic anemia of pregnancy erythropoiesis is normal and iron medication cannot be expected to affect either the anemia in the peripheral blood or the red cell forming tissue in the bone marrow. On the other hand, if the bone marrow reveals a normoblastic hyperplasia and a microcytic and hypochromic anemia in the peripheral blood, iron medication is indicated. This will be followed by a correction of the anemia and the erythroid hyperplasia of a normal type in the bone marrow. The megaloblastic anemia of pregnancy, or, a better term, the megaloblastic marrow of pregnancy is of interest from a diagnostic and a therapeutic point of view since the anemia in the peripheral blood may be macrocytic, normocytic or microcytic. The response to treatment is confusing in the latter 2 instances if the blood alone is studied. If iron is given the anemia does not respond. This is a refractory anemia in a limited sense but should not be confused with true refractory anemia (aplastic anemia with a hypoplastic or hyperplastic bone marrow). The microcytic hypochromic anemia with a megaloblastic marrow will respond to liver therapy. There is no question that many men have encountered cases of this type and have been at a loss to explain the lack of any response following iron therapy but a definite response with liver preparations. A microcytic hypochromic anemia with a normoblastic hyperplasia (normal erythropoiesis) will respond to iron medication, and a microcytic hypochromic anemia with a megaloblastic type of erythropoiesis (pathologic) will react only to liver therapy. The finding of "P. A. polys" in the blood will aid in differentiating a megaloblastic marrow from a normoblastic marrow when the anemia is microcytic and hypochromic in type. Our cases with a slight macrocytic anemia and a normal or hyperplastic marrow of either a myeloid or an erythroid (normoblastic) type recover spontaneously following delivery. These cases are rare in the clinic.

Diseases in the Malay States.—The diseases of greatest importance in the Malay States are malaria, typhoid fever, amebic dysentery, bacillary dysentery, intestinal helminthiasis, the venereal diseases (syphilis, gonorrhea, chancroid, lymphogranuloma venereum and granuloma inguinale), typhus fever, pneumonia, influenza, tuberculosis, dengue fever, filariasis, injuries caused by heat, and diseases of the skin, particularly fungous infections.—Simmons, James S., and others: Global Epidemiology, Philadelphia, J. P. Lippincott Company, 1944.

TAMPONS AS MENSTRUAL GUARDS

ROBERT LATOU DICKINSON, M.D.
NEW YORK

Month by month the "curse" hangs over one seventh of a woman's active life. If strung along in sequent days, the flow would carry on for five full years. Yet of the thirty-five years of menstrual periods, the first six or seven and the last eight or ten are times in which pregnancy is little or not all to be desired and chiefly to be apprehended. Therefore, one third of the span of the function is needless fertility, footing up to fifteen years of all but futile vexation. Even with four pregnancies and full nursings, there are still some four hundred periods in which to use ten guards each, or some four thousand nuisances.

Any venture looking to mitigation of menstruation merits unbiased analysis.

For protection against the four or five days of trickle or gush or stain the requirement has been a roll or pad between the thighs, in a cleft so narrow there is no room for it. With this device every step in walking produces some degree of triple-surface rubbing, and every jounce when sitting produces upward pressing. These may be gratuitous discomforts, since, in the absence of the napkin, there is no contact or pressure of the chair seat against the vulva except in unusual conformations, as shown in an unpublished study of mine.

To the external menstrual guard there are some six objections.

To and fro motion may carry contamination from the anal opening to the urinary and vulvovaginal canals, and from the urinary outlet to the vaginal entrance (figures 1 and 6), a process favored by dampness and warmth, to say nothing of surface irritation. In one questionnaire, notice of chafing runs to 14 per cent.[1]

This region, like the armpit, is especially endowed with glands which give forth odor with hampered ventilation, from perspiration and sebaceous secretion, while stale blood, urine and leukorrheal discharge may be factors. Commercial reports show deodorants bought with napkins by one fourth of the purchasers in one series, by nearly half in another[2] and in a third by 59.8 per cent.[3] Recently, napkins carrying a deodorant have appeared in the market. One fourth of certain tampon users praised the freedom from odor.[1]

The support for this surgical dressing calls for some sort of harness or attachment—strap, girdle and buckles—ill adapted to close fitting or diaphanous modern clothing.

Carriage of unnecessary bulk is a bother; disposal after soiling is a trouble, what with the prohibition on blocking drains. The contrast is strikingly shown in figures 5, and between 6 and 7. (Box sizes are as seven to one figured in lots of twelve.)

Lastly, any external menstrual guard, in addition to applying some degree of heat within a confined space, is responsible for rhythmic play of pressure against surfaces uniquely alert to erotic feeling. This may affect a point projecting nearly to the outside and lying in a crevice into which the band may sink—a point which carries more nerve ends closely packed than any like area—namely, the clitoris (fig. 6). The timing of this combination of warmth, friction and pressure fits the peak of congestion of the external genitals for the monthly cycle. Thus an unavoidable focus of attention on the region is emphasized for four days.

The engineering efficiency—or deficiency of the external guard calls for study. This bulk is worn in order to take care of an amount of fluid smaller than is generally appreciated. The total flow averages 2 to 4 ounces (60 to 120 cc.), which is only up to a half cupful.[4] The first day may yield half the total, or a gush may expel retained fluid, or there may be a pause and resumption. Among 30 women only one fourth ran over 3 ounces and one eighth exceeded 4 ounces.[4] Twenty gynecologic textbooks give a much higher average, the range being from 2 to 7 ounces, as compared with those of the researches here summarized—researches which are not yet sufficient or altogether convincing.

The capacity for absorption for the usual commercial article would allow two to four tampons to take up the total output, so that the common employment of ten to twelve, as with napkins—at a cost from 22 to 36 cents—should provide the desirable changes. For the first day, with its possibility of half the total flow, unless the tampon is replaced often or two are worn at the same time, a tenth to a fourth of the women in various reports use a supplementary or substitute external guard. Home made tampons were reported in use by 37 per cent of users in 1942.[3] (This may account for part of the discontinuance.) The common commercial form is a cotton roll compressed to the size of the last two joints of the little finger (figs. 5 and 8), some being slightly tapered. The variety that has far the largest sales runs in three sizes and is provided with a light inserter for placement at any depth by means of a cardboard tube of glazed surface with a cardboard plunger for expulsion of the tampon into the vagina (fig. 8). Four of the six varieties are absorbent cotton, one of cotton linters, one of crape paper held with a net of threads[4a] (fig. 5). All are provided with a waterproofed string for withdrawal. All but one are compressed. They are packaged with individual wrapping of cellophane or paper or in twos or threes. The length, when compressed, is below 2 inches (fig. 5); the diameters run from ½ to 9/16 inch (12-15 mm.). It is to be noted that the posterior vaginal wall averages 3½ inches (9 cm.) in length, while the breadth of the vagina at its upper end, undilated, averages 2½ inches (6 cm.), which is a fact not generally understood. Under ordinary intravaginal pressures the material does not swell as much as in a glass of water. During the process of removal the passage is to be noted as funnel shaped downward. The outlines in figure 5 show tampons compressed and also pulled wide apart to demonstrate differences in construction, but this size is quite beyond their dimensions when saturated within the vagina. As between external and internal guards, the proportional bulk is as fifteen to one.

The living vagina is something of a *terra incognita* as far as slant, shape and dilatability are concerned, and these are all factors bearing on tampon usage. In the dorsal posture the cavity readily holds 10 cc. and, relaxed, 20 to 45 cc., or from ⅓ to 1½ ounces.[5] In the knee chest posture it holds 2 to 3 ounces (60-90

cc.) but 5 to 10 ounces (145-300 cc.) with its outlet held closed and under pressure (fig. 2). Kolbow [6] found 20 cc. a convenient fill for his 500 x-ray shadows, median and lateral (figs. 2 and 3). The passage, in the

incline, so that the external os lies close to the tip of the coccyx, a situation almost unknown to the pictures in textbooks on anatomy and gynecology, but fully illustrated in my Human Sex Anatomy.[7]

The total channel is most aptly designated by the term vulvovaginal passage. Undistended, the major diameters of the two crevices are set in curious fashion at right angles to each other. The inner aspects of the vulva lie together in the midline of the body; the walls of the empty vagina lie flat crosswise of the body (fig. 3). Only when distended rather fully are the combined passages a continuous tunnel. And this tube exhibits a curve with a moderate hour glass narrowing just within the hymen. Most important is the lateral spread of the passage at its upper end (fig. 3), where it reaches the breadth of 2½ inches (60 mm.) and where such span sometimes permits the retroversion pessary to slip crosswise. The right lateral fornix is usually the deeper and the cervix not in the midline,[6] and the tip of a long tampon slips into the pocket on one side or other of the portio vaginalis, if not behind it.

An important factor is the sling of muscular and fascial layers that sweep downward and backward along the sides and rear of the passage (figs. 1 and 3), forming a sphincter group which retains the tampon within its upper two thirds. The levator ani is pictured for the most part as made up of fan shaped sloping bands with the inner border skirting the sides of the vaginal and anorectal canals. But attention is being drawn more and more to the large numbers of fibers running into the perineal body and into the lateral and posterior walls of the vagina.[8] Hence a new designation is suggested for the group of four muscles that loop around the vagina, maintaining closure of its outlet. The "vaginal sphincter group" would thus be made up of the outer ovals, the deep and superficial bulbocavernosus muscles, plus the pubococcygeal pair, with clearly palpable, thickened inner edges, plus the ischiococcygeals that furnish the inner flattened plane. Indeed, the female pelvic floor is built as if designed to hold a tampon in place in the erect posture, because the vagina lies nearly level on this floor. With any fluid content it becomes the "bowl" of Kolbow,[6] as shown in figure 2, this lesser bowl being supported on the larger bowl, the pelvic floor.

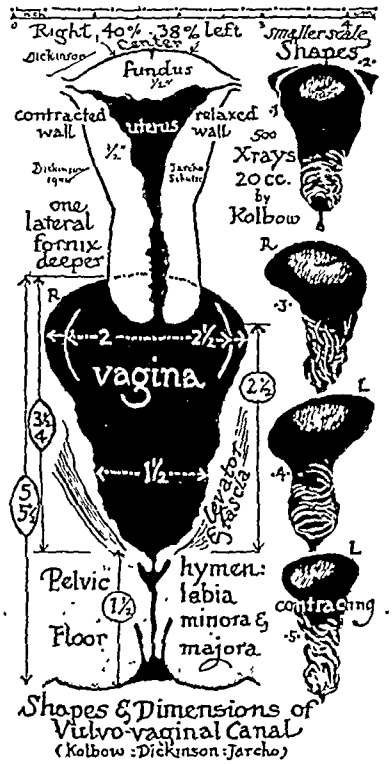

Fig. 3.—Vagina from front to show width at upper end, asymmetry and pelvic floor support for tampon.

Here then is a hollow organ with thin walls endowed with very faint, slow rhythms of contraction; [6] with

sensory fibers of the mucous membrane "meager" in the upper two thirds;[9] so little sensitive "in its deeper portion and farther part of the anterior wall" that one can operate here without anesthesia, the sensory capacity developing "the nearer one approaches to the vestibular orifice."[10] Goodall[11] calls this cervicovaginal district the "great silent area of the pelvis." The vaginal response in coitus belongs to the orifice and to the muscular girdle, as my swab tests show. The erotic stimulus of the stationary interior guard should be, therefore, momentary and negligible as compared with that of the moving pressures of the external pad, on areas provided with remarkably different ratios of sensory nerve endings.

The hymen may, at first touch, be tender like the lining of the eyelid, but it is unlike the conjunctiva in that it can become as tolerant as the mucous lining of the mouth and its lips, what with douching, gentle stretching or good lubrication of the tampon tip, and this without any nick or damage. Only in the hypersensitive or in the rare, thick, rigid form, or the somewhat infrequent substandard opening is stretching needed, begun in the hot bath. The looping muscles just within the hymen (fig. 1) may resist entrance because of a reflex due to apprehension of hurt. There is wide variation here as in all other muscles, for these muscle slings are especially thick and tense in tennis addicts and horsewomen, but any spasm disappears with patient avoidance of urgency.

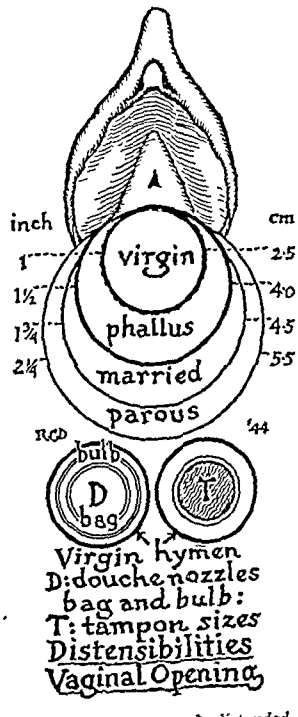

Fig. 4.—Caliber of distended hymen in virginal, married and parous woman, in relation to tampon and douche tube diameters.

A good educator is the douche.

Within the bony walls of the pelvic cavity the organs are provided with capacity for very free displacement, to care for complete filling of the bladder and the rectum and to welcome the to and fro movement of a 6½ inch phallus of a diameter of 1½ inches. Thus room for one or two tampons falls well inside the shifts to which uterus and vaginal walls are keyed.

Concerning the diameters and dilatability of the hymen there has been little published. My long series when pioneer calibrator[7] shows that most unentered hymens admit the average lubricated examining male forefinger for two joints, or the female index entire, the circle having a median diameter of an inch (2.5 cm.) (fig. 4). With the childless married woman two male forefingers pass fully (1½ inches, 4 cm.), which is the peak of the graph of the diameters of the erect penis in the Grien series of 486 white adults[12] and fits the 1,000 of the Kinsey series.[13] Thus the tampon has a caliber that does not impair standard anatomic virginity (figs. 4 and 5).

Unrepaired injuries of labor and sagging vaginal walls may fail to provide support for the tampon. Cervicitis,[14] frequent in the genuine virgin,[14a] or tender uterosacral ligaments, or a sensitive bladder base, or the habitually loaded rectum may exclude tampon usage.

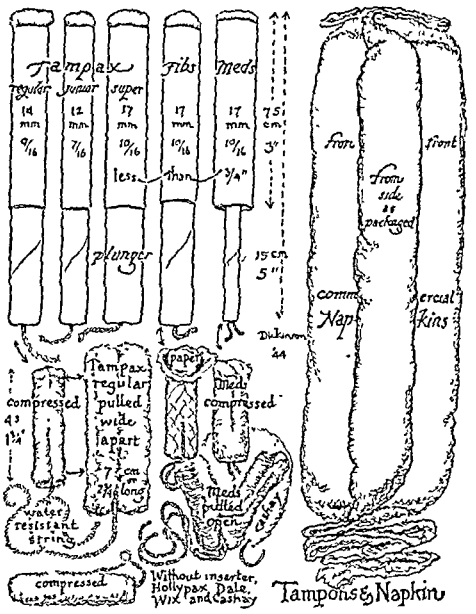

Fig. 5.—Tampons of various makes.

Sales of tampons run to about 10 per cent of sales of commercial napkins. The commercial reports on increase in demand is clinical evidence of value. A continuous survey of 749 drug stores finds the increase all over the country,[15] with 1943 sales five times those of 1937. A

study of 1,674 women made in 1940 found one fourth using tampons, though but few depended on them exclusively, while of the total questioned a fifth had made no trial and a seventh discontinued them.[1] A 1944 survey in twenty-six cities covered interviews with 2,500 women purchasing the two kinds of menstrual protectives.[2] Of these, 24 per cent used tampons, including the third with exclusive dependence, and the two thirds with supplement of a napkin part of the time. Such use was equally distributed between married and single women, the higher the income bracket the greater being the employment of the tampon. The peak of exclusive use was between 20 and 24. Availability of the tampon as guard was known to 94 per cent of those seen, but nearly one third were too apprehensive to make a trial, and inertia and satisfaction with the napkin accounted for 43 per cent of nonusers. Among the 300 who stopped, discontinuance had been due to discomfort in one fifth, to defective protection in another fifth and

Fig. 7.—Tampon in place filled with absorbed flow.

to dislike in one sixth. Recommendation by friends started a third; advice by a doctor was the reason for beginning on the part of 34 out of 900 women, while 11 were stopped in such use by their physicians.

The 1941 research of Karnaky [16] on 2,000 women, covering use for a year or more, included 40 who tested its tolerance by wear day and night. They replaced the tampon twice a day and were examined every two to four weeks for vaginal p_H and for glycogen and had cultures for bacterial growth, with biopsies and also a recording of the visual finding. Karnaky made the sweeping claim that the normals stayed normal, the abnormals became normal, and changes in biopsy and vaginal smear were not found. Also that in 6 patients with profuse bleeding he had packed the vagina snugly during one to six days before opening the abdomen, yet he discovered no evidence of backing up into the peritoneal cavity. Among 110 nurses testing tampon use, he reported 95 per cent satisfied with control all through the period. Sackren [17] reports 90 per cent of users completely protected. Magid and Geiger [18] in 25 women found no alteration in p_H, glycogen or flow and with complete absorption wherever the size of the tampon was correlated with the length and caliber of the

OBSERVATIONS AND METHODS

The clinical features observed especially were (1) weight loss sustained, (2) symptoms and signs of gastrointestinal disturbance such as anorexia, nausea and vomiting and (3) degree of weakness ensuing. Other clinical findings of interest were recorded. The hepatic disturbance resulting was evaluated by (1) the quantitative serum bilirubin test, (2) the cephalin cholesterol flocculation test, (3) the twenty-four hour amount of urobilinogen in the urine and the two hour quantitative urine Ehrlich reaction and (4) the sulfobromophthalein dye retention test.

The level of serum bilirubin was determined by a slight modification [8] of the Malloy-Evelyn technic [9] that permits determination of the prompt direct reacting bilirubin (one minute reading), the delayed direct (fifteen minute reading) and the total bilirubin (reading after alcohol addition). Normal values of the one minute reading range are below 0.2 mg. per hundred cubic centimeters; normal total values are below 1.0 mg. per hundred cubic centimeters.[9a]

The urinary excretion of urobilinogen in the twenty-four hour sample was determined by the quantitative method of Watson.[10] The normal range by this method is 0 to 3.5 mg. in twenty-four hours. A simplified method was later employed.[11] It permits colorimetry of the Ehrlich reaction in a given urine sample. This method, although not precise as far as urobilinogen is concerned, has been found to yield information of approximately the same significance as the twenty-four hour method. The color intensity of the Ehrlich reaction is designated in terms of Ehrlich units, 1 unit indicating the amount of color produced by 1 mg. of crystalline urobilinogen. Amounts in excess of 1 unit in the 2 to 4 p. m. urine sample were regarded as indicating impaired liver function.

The cephalin-cholesterol flocculation test was carried out according to the technic of Hanger.[12] Cephalin, supplied by the Difco Company of Detroit, was used Readings were made at the end of twenty-four and forty-eight hours. As a control, known positive and normal serums were tested concomitantly with the unknown serums.

The sulfobromophthalein test was performed using 2 mg. of the dye per kilogram of body weight and the blood sample secured at twenty minutes. Mateer, Baltz, Marion and MacMillan [13] in their control studies found no retention of the dye at this time in normal subjects.

RESULTS

The clinical data of the 31 patients studied are listed in table 2.

Data of weight loss before and immediately after malarial therapy was obtained in 23 patients, and the average loss was 9 pounds (4 Kg.). Of these patients 17 received general diets and averaged a loss of 10.9 pounds (highest 18½ and lowest 6 pounds) and 6 were given special diets and averaged a loss of 3.3 pounds (highest 4½, lowest 1). Thirteen of the 17 general diet patients received complete or near complete therapy and averaged a loss of 10.4 pounds (4.7 Kg.). Four of the 6 special diet patients were given complete or near complete therapy and averaged a loss of 3 pounds (1.3 Kg.). A comparison of the malarial courses given the general and special diet patients receiving complete or near complete therapy is justified by the fact that the former averaged 9.6 fevers, 42.8 hours of 103 F. and 136.2 hours of 100 F., whereas the latter averaged 9.3 fevers, 40.0 hours 103 F. and 133.5 hours 100 F. (all oral temperature).

The degree of weakness was recorded as severe or not significant. In 5 instances (cases 6, 7, 15, 20 and 23) the extreme weakness, actually prostration, was a major factor in the decision to terminate the malarial therapy prematurely. Ten of 25 general diet patients were severely weakened from malarial therapy, whereas only 1 of the special diet group experienced this degree of weakness.

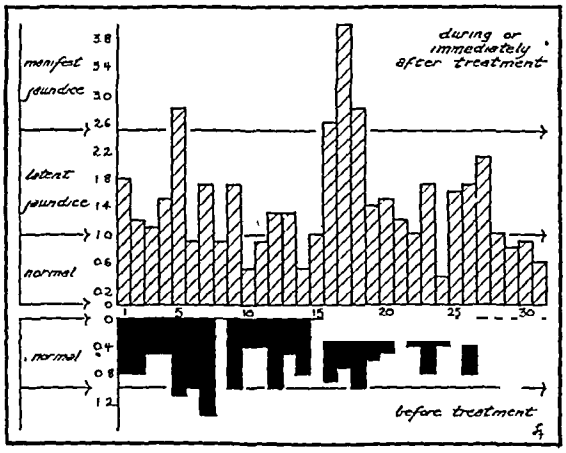

Chart 1.—Quantitative serum bilirubin test reported in milligrams per hundred cubic centimeters; reading at fifteen minutes after addition of Van den Bergh reagent (includes prompt direct and delayed direct reacting pigment); 31 patients.

The gastrointestinal disturbances observed were also considered either severe or not significant. Anorexia invariably developed during malarial fevers. Vomiting frequently followed. These disturbances varied from mild to severe, and in 1 instance (case 20) nausea and vomiting continued four days after termination of the malarial therapy. Seven of 25 general diet patients and 2 of 6 special diet patients had severe gastrointestinal disturbances.

Other clinical findings of interest deserve mention. Purpura, scleral icterus and moderate enlargement of the liver developed in case 5 after eight fevers. Spider nevi developed in cases 7, 9, 13 and 20 after ten fevers. Hepatomegaly during malarial therapy developed in cases 7, 9 and 15. A few spider nevi were noted in case 27 prior to malarial therapy, and other similar nevi developed during the course of her fevers.

The results of the four liver function tests used are depicted in charts 1, 2, 3 and 4 and table 2.

Quantitative serum bilirubin determinations were performed on all 31 patients (chart 1 and table 2). Two patients did not have bilirubin tests before malarial therapy. Twenty-four of the 29 patients studied adequately showed an increase in total bilirubin during the malarial fevers. Elevations to 1.7 mg. per hundred cubic centimeters or more of total bilirubin and 0.6 mg. per hundred cubic centimeters or more of prompt direct reacting bilirubin were considered significant and were observed in 8 cases (1, 5, 9, 16, 17, 18, 23 and 27). Six were general diet patients and 2 were on the special diet.

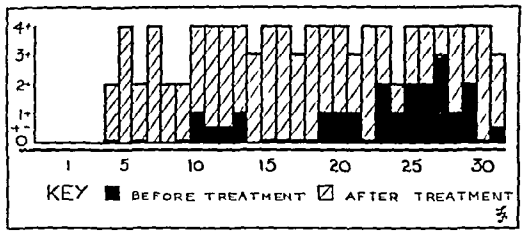

Chart 2.—Cephalin cholesterol test reported in degree of flocculation, reading at forty eight hours, 28 patients.

The influence of malarial therapy on cephalin-cholesterol flocculation is demonstrated by chart 2. The specific data are included in table 2. Eighteen general diet patients and 6 special diet patients developed significant and comparable increases in flocculation. Four general diet patients, not tested prior to therapy, had significant flocculation following their fevers.

Chart 3 shows the urinary excretion of urobilinogen in 24 malarial patients. Thirteen general diet patients were tested by the twenty-four hour method, and significant increases of urobilinogen were noted in 9. The remaining 4 were not tested prior to malarial therapy, but 3 showed excessive excretion of urobilinogen in the course of their treatment. Eleven cases, 5 general diet patients and 6 special diet patients, were tested by the two hour method. Nine of the 11 showed significant increases in urobilinogen excretion. There was no appreciable difference between the general and special diet groups.

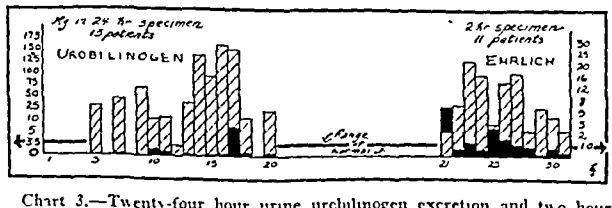

Chart 3.—Twenty-four hour urine urobilinogen excretion and two hour urine Ehrlich values. The data on the right represent Ehrlich units in the 2 to 4 p. m. urine samples. Black areas are observations before malarial fever began.

Chart 4 shows the percentage of sulfobromophthalein retention in 11 patients. Eight were tested before as well as during or immediately after therapy. Five of the 8 showed significant increases. However, in 3 patients the dye retention decreased in the course of their therapy. Again there was no appreciable difference between the general and special diet groups.

COMMENT

Two patients were considered worthy of special mention. Their pertinent histories and findings are given:

CASE 1.—A white woman aged 47, diagnosed as having dementia paralytica, was a chronic alcoholic addict of many years' standing. She was diagnosed as having meningovascular neurosyphilis in 1936 but refused to take antisyphilitic chemotherapy. No clinical liver disease had ever been apparent. Prior to malarial therapy she was considered a good risk. A 9 pound (4 Kg.) weight loss was sustained in the course of nine malarial fevers which terminated spontaneously. At that time the bilirubin test showed a prompt direct value of 0.94 and a total value of 1.76 mg. per hundred cubic centimeters. Her therapy was considered inadequate and she was subsequently given additional fever by typhoid vaccine on three occasions and by artificial fever therapy (hypertherm) twice. A further weight loss of 6 pounds (2.7 Kg.) was sustained. The bilirubin level continued to rise to a height of 1.29 mg. per hundred cubic centimeters prompt direct and a 2.31 total. During her immediate convalescence she stated that she felt the best she had in many years. Forty-three days after malarial therapy jaundice was noted and progressively deepened. The bilirubin, urobilinogen and cephalin-cholesterol tests became very strongly positive. The patient died in hepatic coma fifty-eight days after malarial therapy. Autopsy revealed portal cirrhosis and large areas of acute necrosis.

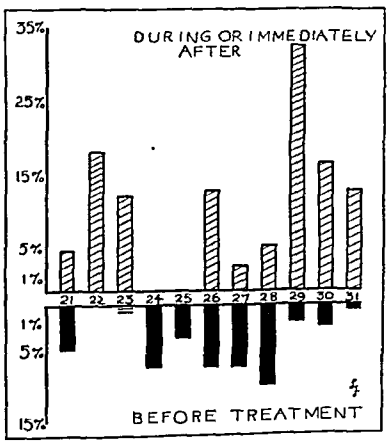

Chart 4.—Sulfobromophthalein retention; readings made twenty minutes after injection of a 2 mg. per kilogram of body weight dose; 11 patients.

CASE 30.—A white man aged 62 was diagnosed as having dementia paralytica. No liver disease was apparent from his past history and clinical findings. He had received fifty to one hundred arsenical injections ten to fifteen years earlier. Prior to malarial therapy the results of the four liver function tests were considered within normal limits. In spite of pure tertian fevers following intramuscular inoculation, considerable weakness, severe anorexia and vomiting developed. A weight loss of 3½ pounds (1.5 Kg.) was sustained. The cephalin-cholesterol test became strongly positive. Quinine was given after nine fevers. During his immediate convalescence weakness and anorexia persisted. A further weight loss of 6 pounds (2.7 Kg.) followed. Urobilinogen excretion was excessive, and 16.3 per cent of the dye was retained in the sulfobromophthalein test. The serum bilirubin remained normal throughout. Liver biopsies taken before and after therapy did not show serious hepatic damage on microscopic examination.

Case 1 demonstrates the need for the detection of latent hepatic disorder. A few simple liver function tests might have forewarned us. Although her need for fever therapy was great, the employment of the liver function tests later used or the more adequate appreciation of the bilirubin values observed would possibly have contraindicated the supplementary fevers given her by typhoid vaccine and the hypertherm. Case 30 illustrates a correlation between clinical findings and liver function tests. However, the liver biopsy after malarial therapy did not show serious liver damage.

It was not possible to correlate consistently the degree of weakness and the severity of the gastrointestinal disturbances with the results of the liver function tests. However, the appearance of jaundice in 1 patient, hepatomegaly in 4 patients and spider nevi in 5 patients correlated strikingly with the hepatic disturbance shown by the liver function tests.

The average weight loss during and immediately after malarial therapy in patients given general diets was very striking. That weight loss could be diminished by special dietary measures was clearly demonstrated. Yet in no case was weight loss prevented. The dietary goal sought for the special diet group of patients was 2,500 calories per day, with 400 Gm. of carbohydrate, 150 Gm. of protein and not more than 35 Gm. of fat. Further study of high carbohydrate, high protein and low fat diets is needed in malarial therapy.

SUMMARY AND CONCLUSIONS

The anorexia and other gastrointestinal disturbances in malarial therapy, if ignored, result in a low caloric intake and a striking weight loss.

More attention should be given to the study and use of protective diets in therapeutic malaria.

Malarial therapy is admittedly contraindicated in the presence of clinically manifest hepatic disease (as, for example, cirrhosis).

It would seem advisable to employ a few simple liver function tests in the selection of patients for this type of therapy. Cases of latent hepatic disease might thus be detected and the clinician thereby forewarned.

The laboratory tests used in this investigation probably represent the more sensitive of the commonly employed liver function tests. Therefore the abnormalities reported are not presumed to indicate irreversible hepatic damage. The occurrence of such changes does not constitute a reason for avoiding the use of a well tried and effective therapeutic agent.

All of the patients adequately studied showed some evidence of hepatic dysfunction.

2437 Third Avenue.

ABSTRACT OF DISCUSSION

DR. L. W. DIGGS, Memphis, Tenn.: The authors have presented further evidence that malaria produces parenchymal hepatic changes with impairment of liver function. Some of the factors in the production of these changes are anemia, deposition of pigment and nutritional deficiencies. The high fevers are also to be considered, for similar changes are observed in artificial fevers. In selecting patients suitable for malaria therapy and for drug testing the more sensitive tests, as the cephalin-cholesterol and twenty minute sulfobromophthalein, are preferred. Since most patients during malarial fevers give positive findings with these tests, they are not of equal value during the febrile period. The icterus index and urinary tests for urobilinogen and bile would be of greater value. The test of the direct van den Bergh reaction of the blood is not necessary, for bilirubin is demonstrable in the urine by the simple foam test when there is regurgitative jaundice. Since malaria produces changes in the blood, it is advised to do the following blood studies on patients receiving malaria therapy: (1) white blood cell count to detect leukopenia, (2) hemoglobin to measure anemia and (3) blood smear to detect hemolytic reaction, neutrophilic shift and degenerative changes, number and types of parasites and number of platelets. Less than 1 platelet per oil immersion field is indicative of thrombocytopenia and may be associated with hemorrhages. I have studied the prothrombin concentration by Quick's method at weekly intervals in 59 patients and have not observed significant decreases during the febrile period. The prothrombin test is therefore of little value as a liver function test either in selecting patients for therapy or in guiding therapy and drug administration. Because the clinical and pathologic changes in terminal malaria are similar to those observed in shock, it is essential that ample supplies of whole blood and plasma be available in

order to prevent death. The giving of arsenicals and heat cabinet therapy following malaria is dangerous and should be used only when there is minimal liver damage as revealed by tests for liver function.

DR. M. G. FREDRICKS, Minneapolis: The main conclusion of the investigation is that there was objective evidence of hepatic disturbance in all therapeutic malaria patients studied with liver function tests.

THE CHEST X-RAY EXAMINATION

AN ANALYSIS OF DISQUALIFYING CONDITIONS FOUND AMONG 105,141 SELECTEES

MAJOR RICHARD E. KINZER
MEDICAL CORPS, ARMY OF THE UNITED STATES

The ultimate effects of the induction into the armed forces of the United States of men suffering from an incipient or a frank form of pulmonary tuberculosis is obvious to medical men as well as to the layman. In addition to the health aspect of this problem as we are affected by it in this national emergency we must take practical cognizance of the economic loss to the national government. Spillman [1] estimated in 1940 that the cost to the government of a case of tuberculosis in a veteran of the first world war was between $7,500 and $10,000 to date and that within the next five years the total cost of service connected disability payments would reach the total sum of nearly a billion dollars. Thus it would seem that from the economic as well as from the health standpoint any program designed for the primary purpose of excluding tuberculous risks from the armed forces would be invaluable.

TABLE 1.—*Analysis of 999 Cases of Pulmonary Tuberculosis Discovered During the Chest X-Ray Examination of 105,141 Selectees*

Tuberculosis, pulmonary		Per Cent of Total Rejectees	Per Cent of Total Rejected for Tuberculosis

But let us recognize that this is only part of the benefits derived from such a program. The preinduction roentgenologic screening adapted by the United States Army has offered innumerable advantages to the roentgenologist in identifying other disqualifying defects of a nontuberculous nature as well. In addition, this program of routine preinduction chest x-rays parallels similar work being done by the various public health agencies in this country and offers to these agencies the results of this massive survey.

In the fall of 1940, when the Selective Service System began functioning, the urgent need for routine chest x-rays at the induction stations became apparent. It was impossible for the armed forces to assemble enough equipment to undertake such a task on short notice. In some localities the public health departments offered their facilities and began taking routine chest x-rays as early as November 1940.[2] By midsummer of 1941 adequate x-ray facilities were at hand, and since that time millions of preinductees have had routine chest x-ray studies.

During the twenty-two months between Aug. 1, 1941 and May 30, 1943 a group of 105,141 selectees were examined by an armed forces induction station team having headquarters in Michigan. The territory served by this station included largely an agricultural and rural section having only one city of over 150,000 population and few others with a population of over 20,000. The fact that this is a sparsely populated section of the state may be significant when comparing the results of

Read before the Section on Radiology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 15, 1944.

1. Spillman, Ramsay: The Value of Radiography in Detecting Tuberculosis in Recruits, J. A. M. A. **115**: 1371-1378 (Oct. 19) 1940.

2. Edwards, H. R., and Ehrlich, D.: Examination for Tuberculosis: Roentgenographic Findings of 41,809 Inductees and 9,541 National Guardsmen in New York City, J. A. M. A. **117**: 40-45 (July 5) 1941.

this analysis with those from other areas which include large cities and more densely populated rural communities. The period August 1941 through May 1943 must also be considered as significant when comparing with other analyses. The standards for acceptance, as outlined in Mobilization Regulations 1-9, were high during a large part of this period, and otherwise healthy young men were being disqualified because they had more than the arbitrary limit of ten intrathoracic calcified areas. These limits were relaxed soon after this country declared war, but the number of men disqualified because of apparently healed primary type tuberculosis still remained relatively high.

The method of examination, which during the past three years has been a topic of great interest, should be noted. The photoroentgen unit, utilizing 4 by 10 inch film with stereoscopic exposures on the same film, was used during the examination of about 80 per cent of the men in this series. When examinations were conducted in a satellite station, single 14 by 17 inch chest films were taken. In all instances single or stereoscopic 14 by 17 inch films were taken in doubtful or suggestive cases.

The results of this program will best be seen in the years to come. For the present an analysis of disqualifying defects found during the actual examinations will be of interest. Local reports and surveys of induction station examinations have appeared in the literature from time to time during the past two years.[3] The material to be presented at this time is only an addition to the surveys already made by others in other parts of the nation.

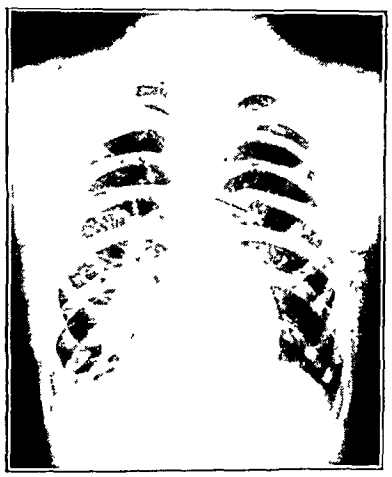

Fig. 1.—Eventration of the right diaphragm.

Fig. 2.—Same case as shown in figure 1, showing stomach located above liver.

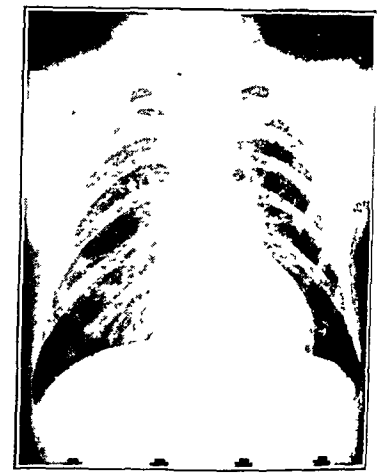

Fig. 3.—Coarctation of aorta.

On the basis of chest x-rays alone 1,328, or 1.26 per cent of the 105,141 selectees examined, were disqualified. Not all of these were permanently disqualified, many being deferred for a period of six months or more because of small lesions which could not be definitely classified as to activity. As no attempt has been made to determine the exact number of men returning for reexamination after having been deferred because of a doubtful lesion, a small number have been counted as chest rejections more than once, thus making some inaccuracy in the tabulation of the number of men rejected because of minimal pulmonary lesions.

3. Ashbury, H. E.; Whildin, J. G., and Rogers, F. T.: Roentgenological Report of Chest Examinations Made of Registrants at U. S. Army Induction Station No. 6, Third Corps Area, Baltimore, Md., May 1, 1941 to March 31, 1942, Am. J. Roentgenol. 48: 347-351 (Sept.) 1942. Levitin, Joseph: Ten Thousand Chest Examinations with the Stereoscopic Photoroentgen Unit, Am. J. Roentgenol. 49: 469-475 (April) 1943

was the basis for rejection of 999, or 75.2 per cent, of those disqualified because of chest x-ray findings. Reference to table 1, showing a further tabulation of the tuberculous lesions, reveals that 60.7 per cent of these were reinfection type, 29.5 per cent were primary infection type, 8.5 per cent were pleural lesions and 1.2 per cent were lesions being controlled with either a therapeutic pneumothorax or a thoracoplasty. It is of particular interest to note further that of the 607 reinfection type lesions 526, or more than 86 per cent, were classified as minimal in extent. The total number rejected for all forms of pulmonary tuberculosis, 999, represents 0.95 per cent of the total selectees examined. This is probably a lower rate than will be found in areas having large cities and is actually not a representative figure for the population in general in this part of Michigan, as local board physicians were actively examining selectees and disqualifying obvious cases of tuberculosis during most of the period covered by this analysis. It is true that local board examinations became more and more sketchy, for obvious reasons, during the latter part of 1942 and 1943, and it may be that in the final analysis a representative cross section of the male population reached the induction station for examination. The fact that 1.2 per cent of those rejected because of tuberculosis were under some form of treatment for the disease bears this assumption out to some extent.

I have said that 75.2 per cent of those disqualified on the basis of chest x-rays had some form of tuberculosis. The remaining 24.8 per cent were disqualified for a variety of reasons, as illustrated in tables 2 and 3. Many of the defects listed in these tables were of course obvious to other examiners on the examining line. Thoracic cage deformities due to thoracic scoliosis and other bone disturbances such as old rickets were not considered as chest x-ray disqualifications, as they were obvious to the general musculoskeletal examiner and could best be evaluated by actual physical inspection plus a review of the chest x-ray. Thus, deformities of the thoracic cage and diaphragm, as shown in table 2, make up a total of only 2.2 per cent of those disqualified by the roentgenologist.

Among those disqualified because of lesions of the heart and mediastinum were many requiring consultation with the cardiac examiners before a diagnosis could be made. On the other hand, cardiac lesions requiring disqualification which had no gross changes in the cardiac silhouette were not included in this list. The coarctations of the aorta listed were only those in which an accurate x-ray diagnosis could be made.

The parenchymal nontuberculous lesions listed in table 3 include some with rather uncertain diagnoses. Many of those called pneumonitis may have been due to tuberculosis. Likewise, those labeled bronchiectasis were not all proved cases, although a good many had been previously so diagnosed by means of bronchography. Chronic bronchitis was a diagnosis arrived at only after consultation with the chest examiner and was considered cause for rejection when associated with asthma.

Neoplastic lesions were very infrequent. Of the two metastatic tumors, one was associated with a hard testicular tumor and was therefore accurately classified. The other was of uncertain origin.

The miscellaneous column (table 3) includes emphysema and pneumonoconiosis. These conditions were infrequent enough to warrant histories and consultation with the chest examiners to substantiate the diagnoses. The majority of those rejected because of pneumonoconiosis had been foundry workers, although a few had apparently acquired the condition as a result of several years' occupation as enamel sprayers.

Foreign bodies in the lungs were cause for rejection only when located in the bronchial system or when surrounded by a local reaction in the parenchyma.

The number of rejections for reasons other than tuberculosis may seem unusually large. A careful analysis of the many disqualifying conditions listed in tables 2 and 3 will reveal that they are entirely adequate causes for rejection. For purposes of illustrating and emphasizing this point, several reproductions of chest x-ray films are presented: figures 1 and 2, eventration of the right diaphragm in which the stomach and portions of the large bowel are located between the high diaphragm and the liver; figure 3, coarctation of the aorta; figure 4, mediastinal lymphoblastoma; figure 5, aneurysm of the thoracic aorta; figure 6, metastases secondary to a testicular tumor (this was missed during the genitourinary examination); figure 7, congenital cystic disease of the lung with fluid levels; figure 8, silicotuberculosis.

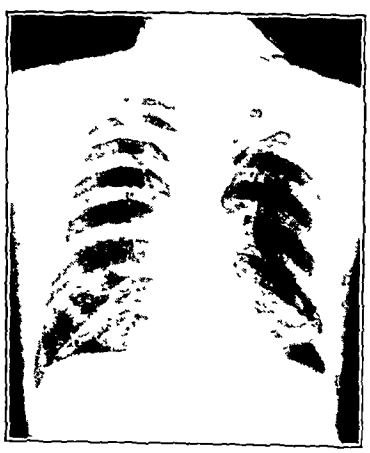

Fig. 7.—Congenital cystic disease of the lung with fluid levels

Fig. 8.—Silicotuberculosis

In addition to the causes for rejection which have been illustrated, the nontuberculous group includes bronchopneumonia, nonspecific pneumonitis and other inflammatory conditions which were the basis for temporary rejection only.

SUMMARY

1. The United States Army, with the early cooperation of the various health agencies in the country, set up and organized facilities for routine chest x-ray examinations in the induction stations throughout the United States shortly after the Selective Service System began functioning.

2. A total of 105,141 selectees were given chest x-ray examinations by an armed forces induction station team in Michigan during the twenty-two months between Aug. 1, 1941 and May 30, 1943. Of this group 1,328, or 1.26 per cent, were rejected on the basis of chest x-ray findings.

3. Some form of pulmonary tuberculosis was the cause for rejection in 75.2 per cent of this total.

4. The remaining 24.8 per cent were rejected for nontuberculous lesions or deformities of the chest.

5. The total number rejected for all forms of pulmonary tuberculosis, 999, represents 0.95 per cent of the total selectees examined.

ABSTRACT OF DISCUSSION

DR. ROBERT G. BLOCH, Chicago: At the University of Chicago we have had some experience with x-ray examinations of the chest among employees and staff members and could match Dr. Selby's stories with some of our own. For instance, the head nurse of the operating rooms at Billings Hospital at one time was found to have active tuberculosis in such a survey. It was found that for months one girl working in the clinical laboratory had contaminated the sputum of nontuberculous patients. They all had been reported to the health department as having tuberculosis. We are now examining all clinic patients by fluoroscopy. Not being a radiologist, I should not like to enter into a controversy as to which is the superior method of x-ray examination from a technical point of view. Our reason for employing it is an academic one: we feel that all medical students should leave the school with a fair knowledge of chest fluoroscopy just as we ask them to be able to do a blood count and urinalysis. The National Tuberculosis Association assures us that the private physician's office is the main tuberculosis case finding agency. He can hardly be expected to buy a 4 by 10 inch fluorogram equipment, but he can be expected to have access to a fluoroscope; to know how to use it will help the private practitioner to keep his place in the future practice of medicine. We have examined about 60,000 persons by fluoroscopy. Joslyn states that 0.4 per cent of the total number of patients seen in medical practice are found to have diabetes by routine urinalysis. The diagnosis of blood dyscrasias found by routine blood counts is of an even lower percentage. Among the expectant mothers in the clinic of the Chicago Lying-In Hospital we find slightly more clinically important tuberculosis by chest fluoroscopy than syphilis is diagnosed by the routine Wassermann test. In spite of this evidence, it occurs to few administrators of medical institutions to introduce this most successful of all routine diagnostic tests. We estimated conservatively that during the first fifteen years of the existence of the University of Chicago Clinics 3,000 clinic patients seeking medical aid for any kind of complaint were permitted to slip by with an actively tuberculous condition of the lungs without that condition being diagnosed. Let us apply that figure to the adult population of the United States; according to the best information obtainable, about 45,000,000 adult people annually are seeking medical aid once or oftener in doctors' offices or clinics. This would suggest that every year over 600,000 people with clinically important tuberculosis of the lungs are seen by a physician without that condition being recognized. If the supposedly healthy population is searched for tuberculosis with so much zeal, we certainly should apply the same methods to the people who report for medical care.

CAPTAIN H. J. PRICHARD, Chicago: I have had experience with induction station chest work and haven't had the ambition to undertake a statistical analysis as Major Kinzer has done, so I can't give you accurate figures; but I did notice that there are some trends that were somewhat different from what he reports. Since I have been with the Chicago station we have examined about 400,000 chests, and we have about twice as many rejects for tuberculosis as Major Kinzer does. We have about 1.75 per cent consistently from month to month. Another difference we have had is in neoplasms. During this series of 400,000 chests the last tabulation showed 53 neoplasms in which dermoids particularly predominated in those cases which we were able to follow through to surgery; and while it was not strictly our business to do it, we did try to get further information voluntarily from these people if they had surgery and were investigated and treated. The dermoids were our most frequent diagnosis. Another condition is coarctation of the aorta. We have accumulated 23 cases of these.

MAJOR R. E. KINZER, M. C., A. U. S.: In comparing this work on chest x-rays, you will always have to consider who is reading them. I worked at all of the induction stations in this service command. I think I worked with Captain Prichard for a short time. I believe that there is a difference in the number of cases of tuberculosis found in a rural district and in a district which is made up of large cities. Apparently there is about 0.78 per cent difference between the tuberculosis rate in large cities and the rate as I found it in rural communities.

DEGENERATIVE ARTHRITIS OF THE HIP JOINT

TREATED BY ONE OR TWO STAGE ARTHRODESIS WITH METAL FIXATION (WATSON-JONES)

G. EDMUND HAGGART, M.D.
BOSTON

Patients with unilateral degenerative arthritis (hypertrophic or osteoarthritis) of the hip joint often exhibit a degree of disability which may be relatively pronounced. This loss of function is primarily the result of pain referred from the region of the hip down the anterior and medial thigh to the knee joint. Muscle spasm producing flexion adduction contracture of the hip perpetuates a vicious cycle because of the resultant abnormal weight bearing on the extremity. While conservative treatment will consistently relieve the severity of symptoms, the results of such therapy have not been permanent. Indeed, usually sooner or later, and as a rule the former, symptoms recur, particularly if the patient is relatively active, as when engaged in a type of work that necessitates long hours of standing and walking about.

The most satisfactory results at the Lahey Clinic have been obtained with fusion of the involved hip, which in the past was secured by a bone graft transplanted from the iliac wing to bridge the prepared area over the femoral neck, head and adjacent ilium. Once a firm arthrodesis developed, the patient was relieved of his major complaint—pain. In the majority of patients so treated there was a good functional result. Our experience with other types of surgical intervention has been unsatisfactory. In none of the patients treated by osteotomy of the femur, either subtrochanteric or between the trochanters, by acetabuloplasty, including removal of hyperplastic bone on the femoral neck and head, or by arthroplasty was pain completely absent.

Conservative therapy, such as bed rest, traction or plaster, including physical therapy, would always ameliorate, at times completely relieve, symptoms, but if the patient was at all active the pain again recurred. Furthermore, these individuals do not tolerate well a long period of bed rest.

It is pertinent to mention the results obtained with arthroplasty. In succession, chromized membrane, fascia lata and finally vitallium have been employed as the interposition medium. In 18 patients of this age group (50 to 65 years) the results have been disappointing when vitallium cup arthroplasty was utilized. All have some pain on weight bearing, and the range of motion is limited. When walking the majority require

From the Department of Bone and Joint Surgery, the Lahey Clinic. Read before the Section on Orthopedic Surgery at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 14, 1944.

a cane and in some instances a crutch. In younger patients (third and fourth decades) with degenerative changes in the hip resulting from such conditions as Legg-Perthes disease, fracture or a slipping of the proximal femoral epiphysis, vitallium cup arthroplasty has produced definite improvement in the function of the joint. I believe the comparatively good results in the younger age group is due to their greater stamina and ability to perform the repetitious and monotonous exercises plus better developed and controlled musculature. The older patients early exhibited fatigue, which became more rather than less pronounced as time went on. Hence this group was simply unable to carry out a most important part of the program, namely exercises in the postoperative period.

These experiences indicated a return to the hip fusion operation. However, in these older patients hip joint arthrodesis, by means of a bone graft, is a formidable procedure. Furthermore, the patient must remain in bed in a bilateral hip spica followed by a single spica for a minimum period of three to four months. Vigorous individuals may become ambulatory after application of the single spica, but even so it is a debilitating experience. Return of the normal knee joint function was often long delayed after the patient was out of plaster, in spite of the fact that metal hinges, as suggested by Leland,[1] were routinely incorporated in the single plaster hip spica case, to permit relatively early motion, after weeks of complete immobilization.

It was finally decided to treat those patients selected for operation by the method of Watson-Jones,[2] since he stated that the procedure was especially applicable to degenerative arthritis of the hip joint. Watson-Jones presented this operation before the Section on Orthopedic Surgery of the American Medical Association in 1938.

A review of American literature reveals one paper on this method, that by Warren White,[3] who reports satisfactory results in 7 hips, 2 of which were considered tuberculous. White employed the one stage procedure, that is, nailing only, and stressed the resultant prevention of an adduction deformity, especially in the growing period.

This paper is a report of our experience with this operation, in most instances a two stage procedure as described. Although the number of cases is small, they have been carefully observed and the results are decidedly encouraging. The use of this method will be continued because it causes a fusion of the hip—as noted, the most satisfactory therapy in unilateral degenerative arthritis of this articulation—and, furthermore, hip arthrodesis is obtained with a comparatively minimal degree of bed rest, knee joint disability and general debility.

The belief that a patient with an ankylosed hip would of necessity have pain in the low back has frequently deterred us in the past from advising and carrying out an arthrodesis of the hip joint. We then subscribed to the belief that because a stiff hip placed an increased strain on the low back and hence would produce pain, particularly if the patient had some arthritic changes in the lumbosacral spine, an operation designed to fuse the hip joint should not be considered. However, as Watson-Jones pointed out, in the presence of a unilateral arthritic hip this articulation could be ankylosed and hence symptoms and muscle spasm relieved, with the result that the patient not only has no pain in relation to the hip joint but also does not develop a painful low back. Furthermore, because of the absence of muscle spasm, the individual often will exhibit an increased range of motion in the low back. This fact was becoming increasingly apparent with the utilization of a bone graft to obtain hip fusion. Consequently, since the method of Watson-Jones offers a simpler procedure to obtain that end result, it was decided to try it out in selected cases.

SELECTION OF CASES

Patients with arthritic involvement of both hip joints are not suitable cases for arthrodesis. The optimum type is the individual in whom only one hip is involved. No patient is operated on until careful medical study has shown that his condition will permit such major surgery.

The type of patient selected for fusion operation is indicated by a brief outline of a typical history, together with the significant data. Such a patient is a relatively vigorous person in good general health, between the ages of 50 and 65, who seeks medical advice because of disabling hip pain on weight bearing and progressive loss of ability to stand and walk. Examination reveals moderate to pronounced flexion adduction deformity of the involved hip, with considerable limitation of motion. The leg is held in 10 to 20 degrees external rotation, and there is obvious atrophy of the musculature of the buttocks and thigh. Roentgenograms of the affected hip joint exhibit a narrow joint space, with proliferative bone changes and cystic degeneration in both the acetabulum and the femoral head.

OPERATIVE TECHNIC

In the majority of patients submitted to surgery, the operation is carried out in two stages. The first stage is an intra-articular arthrodesis, while in the second stage, performed at the end of ten days to two weeks, a flange nail (Smith-Petersen) is passed through the trochanter, neck and head of the femur and into the dense bone of the ilium just superior to the acetabulum. The one stage operation, that is, pinning alone, was employed only when the patient's condition did not permit a more extensive procedure.

First Stage.—The hip joint is exposed by the usual anterior incision. This entails subperiosteal reflection of the tensor fasciae latae and a part of the gluteus medius muscles from the lateral aspect of the ilium, while the distal portion of the incision is deepened down to the hip joint between the sartorius and the tensor fasciae latae muscle. The rectus muscle is then reflected distally after division of its tendon insertion into the anterior inferior iliac spine—the anterior superior joint capsule is excised and the head of the femur dislocated from the acetabulum. Any loose bodies in the acetabulum are removed, while hyperplastic synovial membrane is cut away from the neck of the femur and acetabulum (fig. 1).

The exostoses and cartilage on the head of the femur are cut away, first, by chisel, and this completed by the use of a cup reamer, modified from the type originally devised by Murphy. Every effort is made to retain the relatively normal contour of the femoral head, at the same time reducing its size to a minimum consistent with exposure of raw bleeding bone. During this step it is important that the acetabulum be packed off with saline moistened gauze to prevent fragments

3. White, J. W.: Smith-Petersen Nail Fixation in Hip Disease, South. M. J. **36**: 333 (May) 1943.

of cartilage from falling therein, which later might be missed. With a motor driven 1/16 inch bit, numerous channels are driven through the head of the femur well into the neck, thus aiding in rapid vascularization. And finally, by means of a small V shaped chisel, the entire articular surface of the femoral head is successively elevated, that is, "shingled" throughout. The object of these steps is to produce more rapid bone growth across the joint line.

By means of a motor driven burr the cartilage of the acetabulum is next removed, and at the same time ridges or pockets in the bone of the cavity are obliterated, so that the articular surface of the acetabulum presents a uniform, even, raw bleeding bone surface. Particular care is taken to remove all cartilaginous and bone débris. Then with a 1/16 inch bit, multiple holes are drilled in the floor of the acetabulum, penetrating both diploes in order to hasten vascularization and hence fusion, which is additionally expedited by permitting the soft bone shavings resulting from the use of the bit to remain in the acetabulum.

The head of the femur is now replaced in the acetabulum and the wound closed. A Penrose rubber tube drain, removed in twenty-four hours, is efficacious in preventing an accumulation of serum. In obese patients a single plaster hip spica is applied, while in slight or more easily handled individuals Russell skin traction to the extremity has often been instituted. In the average case, however, use of the plaster spica has been more satisfactory, as it permits repeated change of the position of the patient with minimum pain and discomfort.

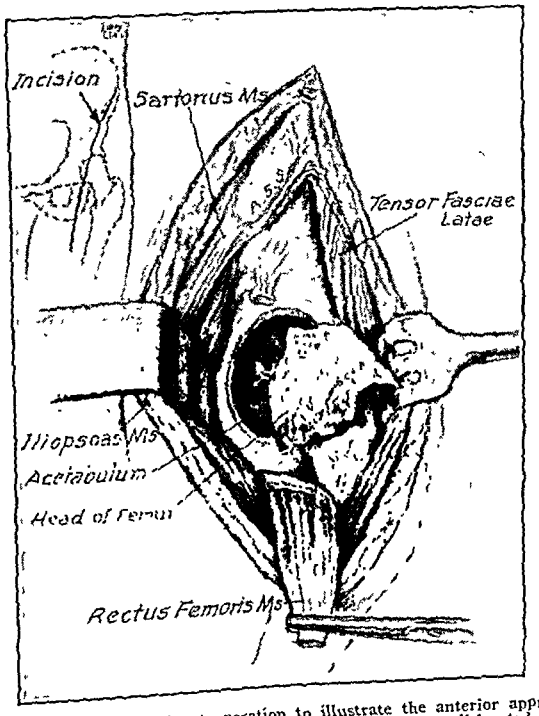

Fig. 1.—Drawing made at operation to illustrate the anterior approach to the hip joint. The head of the femur has just been dislocated from the acetabulum. Note the degenerative changes. See text for technical details.

Second Stage.—Ten days to two weeks later the second stage operation is performed, this time on the fluoroscopic table, again under spinal anesthesia (fig. 2). This procedure utilizes essentially the same technic so commonly employed in nailing fractures of the femoral neck. Under intermittent fluoroscopic observation a guide wire is passed into the center of the neck and head of the femur, up to the articular margin, and the correct position determined in relation to the dense iliac bone just above the acetabulum. The length of the nail required is estimated by a measuring rod photographed on x-ray film, as well as by checking the measurements of a guide wire. A cannulated Smith-Petersen flanged nail is then introduced through a small incision over the lateral aspect of the trochanteric area and driven in along the guide wire through the trochanter, femoral neck and head and into the bone of the superior acetabulum.

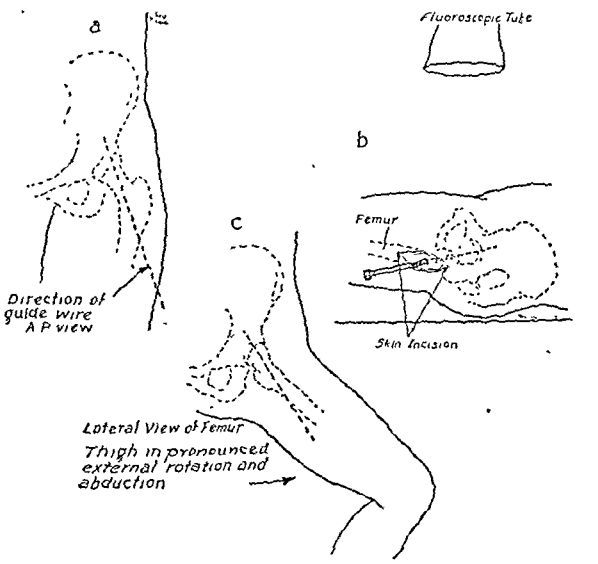

Fig 2.—Line drawing to illustrate the various steps in the second stage procedure. The broken line indicates direction and position of the guide wire, as described in the text, and is introduced only up to the articular margin of the femoral head, thus permitting easy visualization in the lateral plane by "frogging" the hip. A Smith-Petersen nail is then introduced over the guide wire, and it is important to note that it terminates in the lateral portion of the superior acetabular region, where the iliac bone is particularly dense (see fig. 5).

By introducing the guide wire up to the articular margin of the femoral head the entire second stage procedure can be rapidly carried out. With the wire in this position it is possible not only to visualize the trochanter and head and neck of the femur in the anteroposterior view, but by "frogging" the hip joint a true lateral perspective of the position of the wire in the femoral neck and head is obtained. Thus centralization of the guide wire is secured in relation to the femoral neck and head, while in the anteroposterior fluoroscopic view the relation of the wire to the iliac bone above the acetabulum is likewise determined.

Undue exposure of the patient to x-rays from the use of the fluoroscope is prevented by short, intermittent observations, while the operator's hands at no time come into the fluoroscopic field, because of the type of instruments employed. They were designed by Warren White[4] for nailing fractures of the femoral neck and, in my opinion, are an indispensable part of the equipment for the operation here described.

Before driving the nail through the head of the femur into the ilium, it is important that the position of the extremity be carefully rechecked in relation to the trunk. The most satisfactory position is that of 30 to 35 degrees hip flexion, neutral rotation and midposition to 5 degrees abduction.

The final step is firm impaction of the head of the femur against the surface of the acetabulum, following which the small lateral wound of the thigh is closed

4. White, Warren: Personal communication to the author.

and a short plaster hip spica applied. Application of a long leg plaster spica has not been found necessary, since the nail controls any tendency toward rotation and adduction. A short hip spica, however, has been most helpful, as in many of these cases the iliac bone in particular was found to be so decalcified that even with the nail in situ a certain amount of actual hip motion was possible, especially in the anteroposterior plane. No attempt has been made to transfix the head of the nail in the lateral cortical shaft of the femur. To date, none of the nails have extruded or tended to slip back.

Following the second stage operation, the average patient treated by this technic has been kept in bed for two to three weeks, during which period muscle exercises are begun with particular reference to development of quadriceps function and knee joint motion. These exercises are continued a minimum of three months. When allowed up in a single short hip spica, the patient begins progressive walking with crutches. Since immobilization by a long plaster hip spica is unnecessary, knee motion has been maintained in all patients.

STATISTICS

The findings on 12 patients following operation have been carefully observed over a one to five year period, and the results obtained are decidedly encouraging. The favorable results in these patients with degenerative arthritis of one hip joint offer a sharp contrast to the present status of individuals afflicted with a similar type of hip disability who have been treated by other methods (figs. 3, 4 and 5).

The average age of this group is 56 years. The oldest patient treated was 68 years. The operation was advised on the basis of pronounced to complete disability because of hip pain which had been progressive over an average period of four years.

The complication of intratrochanteric fracture due to a fall has so far not occurred It is believed that insistence on postoperative walking with crutches from four to six months has prevented such falls and hastened fusion of the hip joint; furthermore, the use of crutches has been a decided aid in permitting early ambulation as well as assistance in regeneration of muscle power.

ONE STAGE PROCEDURE

The one stage operation was employed when the patient was considered a poor surgical risk but was

Fig 3.—Appearance of the hip joint of a housewife aged 50 who was completely disabled by pain adduction and flexion deformities of the left hip, progressively more severe since fracture of the neck of the left femur three years previously. The fracture had been nailed elsewhere; the nail is still in place. Note pronounced loss of joint space, cystic degeneration in the head of the femur and proliferative reaction around the adjacent acetabulum.

in great pain that was not relieved by adequate conservative treatment.

Three patients were operated on by this procedure, that is, passing a Smith-Petersen flanged nail through the base of the trochanter, neck and head of the femur into the iliac bone just above the acetabulum. The time required to obtain hip join anklyosis was over twice as long as the period in which firm joint fusion was secured by means of the two stage procedure. The latter varied from three to four months. Another

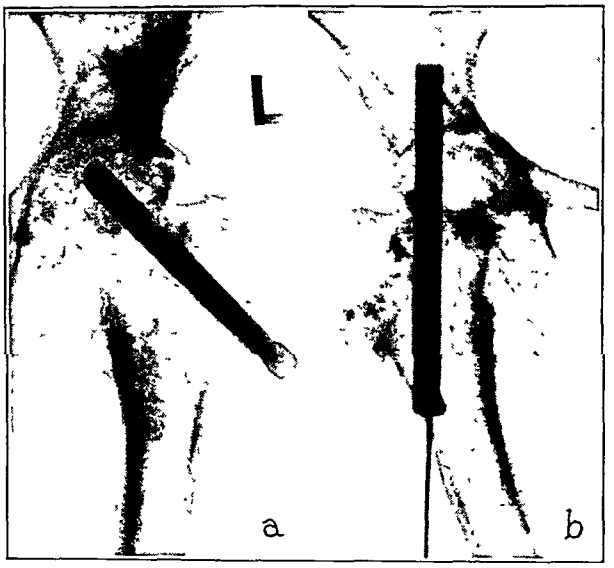

Fig. 4.—Angle at which the pin is best inserted for ankylosis of the hip *a*, condition on admission Pin was inserted elsewhere for fracture of the neck of the femur. The pin was withdrawn at the first stage arthrodesis procedure *b*, final stage of arthrodesis as described in text. Note that the pin terminates in the dense iliac bone just above the acetabulum. Guide wire has not yet been withdrawn, nor has head of femur been impacted against the acetabulum. Compare with figure 5.

obvious disadvantage encountered in these 3 patients, was the fact that, even under anesthesia, practically no correction of the existing deformity, that is, hip flexion and external rotation of the leg, could be obtained. Hence, fusion of necessity had to occur in this abnormal weight bearing position.

RESULTS

Ten patients obtained a painless, solidly ankylosed hip joint, resulting in a decided increase of activity and ability to carry on previous occupations. In each instance the knee joint function equaled or exceeded in range that present before operation. Previously present low back symptoms were not exaggerated.

There were two failures. The data on these individuals are presented in case histories:

CASE 1.—M. N. B., a housewife aged 57, admitted to the clinic on March 10, 1942 with a complaint of pain and practically complete disability in relation to the left hip joint, stated that in July 1940 she had a severe fall down a staircase and sustained a fracture of the left hip She was admitted to a hospital in a neighboring town, operated on and the fracture pinned, and allowed on her feet in four weeks. No further discomfort was experienced until five months later, when she caught a severe cold and then developed a stiffness of the hip which rapidly developed into a completely disabling pain. This had continued until just prior to admission, when the pin had become loose, and it was therefore removed

On admission she exhibited decided limitation of motion in the affected hip, with pronounced muscle spasm. The roentgenogram (fig. 6*a*) revealed an old fracture through the neck of the femur which had healed in good position. The site of the previously placed internal pin fixation can be seen. The films further exhibited an area of considerable density in the head of the femur, indicating that a portion of the head had

not revascularized as well as an extensive degenerative arthritis of the hip joint.

The first stage operation was performed on May 4. A large fragment of the head was found to be definitely necrotic and therefore removed and replaced by bone transplanted from the adjacent ilium. The second stage was done ten days later.

Since that time the patient has not been free from discomfort and at present is again in the hospital because of a failure of fusion (fig. 6 *b*). We now plan to carry out a bone graft to obtain complete fixation of the hip joint.

Failure of hip joint ankylosis in this case was due to the very large bone defect resulting from avascular necrosis of a considerable segment of the head of the femur. Although an attempt was made to replace this dead bone fragment with bone transplanted from the adjacent ilium, it was not successful.

CASE 2.—A. N. C., a housewife aged 60, admitted to the hospital on May 12, 1943, gave a history of three years' progressively increasing pain in the right thigh and hip, so that at the time of admission she was completely incapacitated.

Clinically and by roentgenologic examination the patient exhibited an advanced degenerative arthritis of the right hip joint, with pronounced flexion adduction contracture and external rotation of the leg. She was exceedingly fragile, obviously very arteriosclerotic, and apparently in great pain. For one month the patient was maintained on conservative management, during which interval she did not improve. Therefore, after additional consultation with the medical service and with her family, it was finally decided to carry out a one stage procedure and pin the hip in the position of deformity with the hope that such fixation would reduce pain and discomfort.

The patient was therefore operated on on June 12; a one stage procedure was carried out in which the hip was pinned without incident. She recovered from operation without surgical complications, but her preoperative disorientation became more pronounced and it was in no sense possible to enlist her cooperation in carrying out exercises or progressively increasing her activities.

While a subsequent report from the patient's home physician indicates that by roentgenologic examination she has an ankylosis of this hip joint, nevertheless

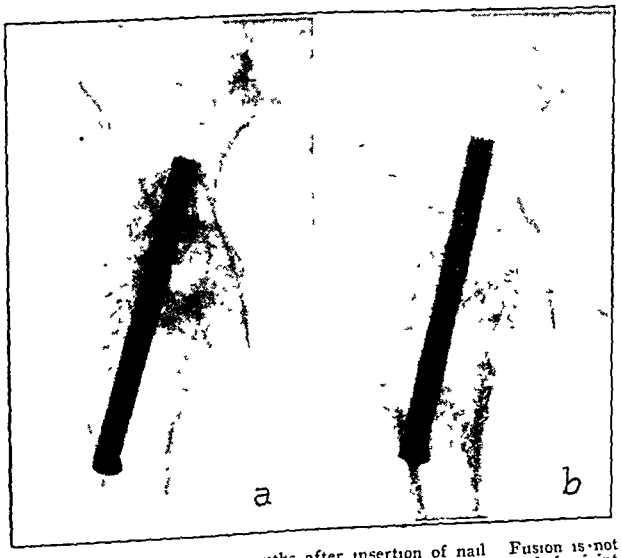

FIG. 5.—*a*, condition two months after insertion of nail. Fusion is not yet complete but is rapidly progressing. The superior aspect of the joint line is obliterated. At this time the patient was clinically free from symptoms. *b*, ten months after operation. Solid bone ankylosis of hip joint. Position of nail remains unchanged.

the result is a failure because of poor selection, due to extensive arteriosclerosis with consequent brain changes that prevented the patient from cooperating in her postoperative management.

SUMMARY AND CONCLUSIONS

Unilateral degenerative arthritis of the hip joint often results in disability which the patient attributes to pain in the region of the hip and referred down the anteromedial side.

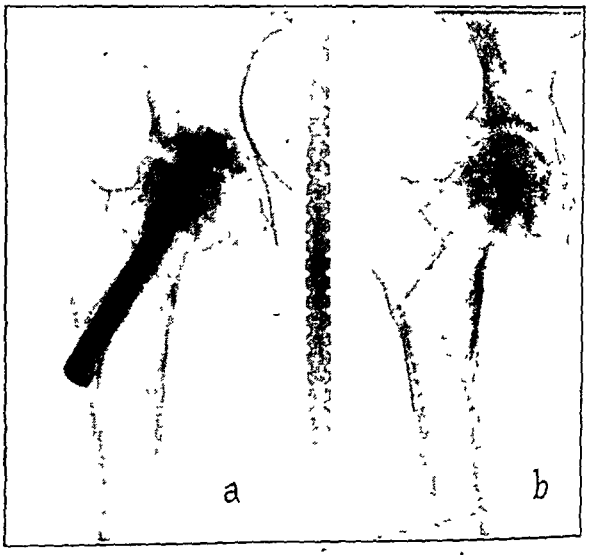

FIG. 6.—*a*, appearance on admission. Note large area of bone sclerosis in the superior portion of the femoral head and cystic areas of degeneration in the remainder of the head. Notched metal bar, an additional aid in measuring length of nail, is described in text. *b*, failure of fusion twenty-two months postoperatively. Note bone absorption about the pin (see text).

In our hands patients within the age group of 50 to 65 years have not obtained permanent relief by conservative treatment nor has arthroplasty eliminated pain. The best results followed arthrodesis of the hip joint, which operation in this age group is now performed in two stages.

It is important to note that no patient is advised operation unless a general medical examination indicates that his condition will permit such treatment.

The course of 12 patients in the age group 50 to 65 has been followed for from one to five years. There were no operative fatalities. Ten patients obtained firm, bony ankylosis of the hip joint and subsequent complete relief of pain, definite improvement in function and the ability to return to their previous activities. There were two failures.

605 Commonwealth Avenue

ABSTRACT OF DISCUSSION

DR. DAVID M. BOSWORTH, New York: Operative intervention on these old people is a grave risk, not on a percentage basis, because the percentage of deaths is small, but in the individual case. Basically the patient has to risk his life to free himself from pain. So, fusion of a hip by any method is a relatively important decision for both the patient and the doctor to make. Dr. Haggart probably would prefer fusion with an iliac or other bone graft were such procedure not more difficult and lengthy. I would be glad to have him comment on this. He states that his experience with other types of surgical intervention (arthroplasties) has been unsatisfactory. At St. Luke's we would concur with that statement. All other types of reconstruction for degenerative arthritis of the hip aside from arthrodesis were unsatisfactory, and we have tried many methods. I would question the efficacy of his one stage procedure. Metal never grows bone. I am not in agreement that driving metal nails across hip joints with residual cartilage intact will secure anywhere near the percentage of solid arthrodeses that a débridement of the joint and a bone graft will. Metal does permit fixation and is a great adjunct for

fixation. Therefore I do not agree that his two stage operation might equal the percentage of results secured by fusion with a bone graft. End result studies not based on recent personal follow-up study of the patient are apt to be misleading. What were some of the complications that ensued? Were there any hematomas or any infections following the removal of drains? Was there any difficulty with wound healing? What was the final position of the hip as compared with the position you put it in? Did any of them roll out to a position of external fixation; did increased flexion take place? Did any of the nails wander from their immediate operative position? A nail with only an inch support in the ilium might shift its position over a period of months. Were there any cases of impaired knee function? I still believe that, in arthrodesis of the hip, iliac grafts or grafts of bone are best, associated with thorough débridement of the joint space.

DR. HERMAN C. SCHUMM, Milwaukee: Dr. Haggart's success was due to the thought and care which he gave to the individal case. In all cases of hip surgery the careful consideration of the patient, which means a careful selection of the patient for the particular type of operation, is the prime requisite. Dr. Haggart has certainly carried out that requisite. There is no question also that his surgical technic is excellent, which is an aid to any surgical procedure. The Watson-Jones operation has its place. There are cases in which a definite arthrodesis cannot be done because of the physical condition of the patient or probably because his life has to be so regulated that he does not have to carry on a strenuous physical life. Those cases can sometimes be helped by a single nailing. Dr. Haggart gives a great deal of credit to Watson-Jones for his operation. If one is going to obtain maximum results in a large majority of cases one is going to have to resort to firm ankylosis. For patients who have a great deal of activity ahead of them, whose physical condition is excellent, there is no operation that can take the place of a good arthrodesis. None of our classic types of operation that attempt to preserve motion will fill the bill. Under the stress and strain of years they are bound to give way, and pain is bound to recur. I should like to ask Dr. Haggart his reasons for doing a two stage instead of a one stage operation. Some cases that are nailed will never go on to an arthrodesis. In a small series that I have done, firm arthrodesis has resulted; 1 patient was probably tuberculous and 2 had arthritis, a young child who had considerable erosion of the hip and a young man who had trouble from childhood.

DR. J. WARREN WHITE, Greenville, S. C.: There is no question about the desirability of doing an intrajoint arthrodesis, but some patients cannot stand that major procedure, and so I have in 1 instance used two nails. Watson-Jones used a supercaliber nail, which cannot be obtained easily. I had a regular nail break, as you will note from my paper on the subject that came out a year ago, and I decided I had better employ something else and hit on the idea of using two nails. I have packed in two nails, and I think I obtained good solidity.

DR. WALTER BLOUNT, Milwaukee: I question the need for an intra-articular operation in most cases. There is no doubt that more rapid fusion is obtained following the removal of the articular cartilage. It has been repeatedly shown that this operation alone is not sufficient. Internal fixation is a valuable addition. It is my contention that, if this internal fixation is adequate, removal of the cartilage is not necessary. If one wishes to fasten two boards together so that they will not move, one does not put a single screw, nail or bolt in the center of the board. Not even one Smith-Petersen nail will hold them. Dr. Haggart notes that motion at the hip following operation requires the application of a cast. Two or more nails will effectively hold the boards securely. Two nails, as suggested by Warren White, are definitely better than one. I prefer to use multiple adjustable nails. I started by using three. Fixation is obtained but the nails do break. I now use more and heavier nails with great confidence. It is imperative that nuts be used if the nails are to be prevented from wandering inward. A lateral view can be obtained by the use of an orthopedic table with a wooden post. The nails must be accurately placed if firm immobilization is to be obtained. The average stay in the hospital is two weeks. I have not used a cast in any of my cases. I feel that the postoperative complications are greatly reduced. Another reason why I prefer the smaller nails is that they can easily be drilled into the sclerotic bone, whereas it is sometimes difficult to drive any type of a nail into this substance. It is advisable to drill extra holes across the joint to encourage ankylosis. In some of my cases I have x-ray proof of bone union. It may take several years for the hips to fuse. In the interval they are solidly nailed and the patients walk without crutches after six months. It may be that some of the cases develop fibrous union rather than complete bony ankylosis. In any event they are relieved of pain. Their gait is greatly improved. Their deformity is reduced. The patient's symptoms are relieved by an operation which is far less formidable than an intra-articular fusion.

DR. G. EDMUND HAGGART, Boston: In reply to the questions of Dr. Bosworth, Dr. Blount answered one. I would prefer to employ a bone graft, but the type of patient here described does not react as favorably—at least in my hands—as with the two stage operation. One definite failure of fusion was described. The second case was a failure because of poor selection, but fusion of the hip joint was obtained. Two other patients I have not had the opportunity to examine personally, but I have received reports from consulting physicians that the roentgenograms reveal strong, firm fusion and the patients are free from any symptoms with reference to the hip joint. Infection occurred in 1 case, fortunately only of the small incision on the lateral side of the thigh. The incision of the original first stage procedure healed perfectly. Infection occurred as a result of poor technic. I have always found the fluoroscopic room a difficult place in which to keep the operative field sterile. This wound has now remained healed five months. Roentgenograms did not reveal any evidence of bone infection. There have been no pulmonary complications of any kind in this group. Why the two stage procedure? Because these patients react more favorably under that regimen than after a one stage operation. In patients more recently operated on, the entire procedure has been carried out at one operation and they have not done as well as similar types of patients treated by the two stage procedure. The operation can be done in one stage, but these people are very fragile and I believe that the two stage operation works out much better than when the operation is performed all at one time. With the exception of the two failures, all the remaining patients have returned to their previous activities. They have other complaints, but not in relation to the hip or as a result of surgery on the hip joint. I agree with Dr. White and Dr. Blount that you would probably obtain better fixation with two nails than with one nail. However, performing the operation in the manner described in the paper achieved the objective, namely hip fusion. I have had no experience with more than one nail. In a number of these patients, immediately following introduction of the nail there has been obvious definite motion at the hip—not abduction, adduction or rotation, but demonstrable anteroposterior motion. I attribute this to the fact that the bone is soft, as is often the case with these older persons. This is the reason for applying the short plaster spica following the second stage procedure. I consider this spica extremely important. Likewise the fact that we have insisted that the patients use crutches with progressive weight bearing for an average period of six months has been of additional aid in preventing complications. However, the patients are up and about, out of the hospital. This activity has also prevented complications that might otherwise have arisen. Dr. Blount certainly has hip joint fixation, but it seems like a considerable amount of hardware. I prefer the simple Smith-Petersen nail.

Strength of Sunlight.—Artificial light, even if perfected to the highest degree, has never the strength of sunlight and is more fatiguing to the eyes, as it does not stimulate the retina by a constant change of the intensity and color of the light rays, as does daylight. Every sensitive person will rejoice to see sunlight again when he comes out of an artificially lighted museum into the day.—New Architecture and City Planning, A Symposium, edited by Paul Zucker, New York, Philosophical Library, 1944.

ONE DOSE PENICILLIN TREATMENT OF CHRONIC GONORRHEAL VAGINITIS IN CHILDREN

WALLACE SAKO, M.D.
ROSS TILBURY, M.D.
AND
JESSE COLLEY, M.D.
NEW ORLEANS

The treatment of chronic gonorrheal vaginitis has undergone rapid changes in the past few years. Sulfonamide therapy has brought rapid cure of this stubborn disease in the majority of instances. However, since several cases have been found to be sulfonamide resistant, estrogen therapy (diethylstilbestrol) has been recently advocated. With the advent of penicillin, it seems quite evident that this drug is by far the most effective and the safest to use in the therapy of gonorrheal infections.

It is our purpose in this paper to describe our experience with a simplified one dose penicillin treatment of chronic gonorrheal vaginitis. The results in 16 cases show that patients with this chronic disease need no longer be hospitalized but can be satisfactorily treated in the office and rapidly cured.

From the Department of Pediatrics, Louisiana State University School of Medicine and the Charity Hospital of New Orleans.

To conserve time and space, pertinent facts regarding our 16 cases are presented in tabular form.

Children with Chronic Gonorrheal Vaginitis Given One Dose of Intramuscular Penicillin 100,000 Units

Patient	Age	Race	Duration of Disease	Diagnosis by		Previous Therapy		Penicillin Intramuscularly	Results		
				Smear	Culture	Sulfonamide	Diethylstilbestrol		Vaginal Discharge	Smear	Culture
1. C. J.	1 mo.	Negro	Since birth	Positive	Positive	Sulfathiazole 2 wks.	None	100,000 units in saline solution	Cleared in 2 days	Negative for 3 wks.	Negative
2. B. J.	1 mo.	Negro	Since birth	Positive	.....	Sulfathiazole 4 days	None	100,000 units in saline solution	Cleared in 2 days	Negative for 2 wks.	
3. E. M. S.	1 mo.	Negro	Since birth	Positive	Positive	None	None	100,000 units in saline solution	Cleared in 72 hrs.	Negative for 1 mo.	Negative for 1 mo
4. M. B.	6 mos.	Negro	5 mos.	Positive	Positive	Sulfathiazole 1 mo	3 mos.; stopped due to vaginal bleeding	100,000 units in saline solution	Cleared in 48 hrs.	Negative for 3 wks.	Negative for 3 wks

COMMENT

Diagnosis was established by smear only if the case was clearcut and gram negative intracellular organisms were found in pus cells. In all other instances diagnosis was made both by smear and by culture. Most patients received sulfonamide and/or estrogen therapy for varying periods of time prior to institution of penicillin therapy. Sulfonamide therapy was discontinued either because of toxicity or of failure to respond. Estrogen therapy was discontinued because of failure to respond, lack of cooperation or uterine bleeding (cases 4 and 6). Sulfathiazole and sulfadiazine were given in doses of 1 grain (0.06 Gm.) per pound daily divided into four equal doses and administered at 8 a. m., 12 noon, 4 p. m. and 8 p. m. Estrogen therapy when instituted was generally given after sulfonamide therapy. Diethylstilbestrol was given orally in doses of 1 mg. daily.

Penicillin therapy was not started until all other forms of treatment were discontinued for at least one week. Penicillin 100,000 units was dissolved in 20 cc. of isotonic solution of sodium chloride and injected intramuscularly. In a few instances 3 minims of epinephrine 1:1,000 was added to the penicillin solution in order to prolong the penicillin effect. The

vagina was carefully examined for discharge every day. No local or systemic therapy was given during penicillin treatment. Smears and/or cultures were taken every other day for the first week and weekly thereafter. All except 6 patients were hospitalized for treatment. The 6 patients treated as ambulatory responded just as well as the hospitalized patients. Only one failure (V. H. D., patient 13) occurred out of 16 treated. This patient was promptly cured after she received eight doses of penicillin, 10,000 units every three hours. No toxic symptoms were noted with penicillin.

SUMMARY

Sixteen cases of chronic gonorrheal vaginitis in children were treated with one dose of penicillin, 100,000 units injected intramuscularly. Clinical and bacteriologic cure was effected in 15 cases within three days, usually two days. The 1 remaining case required further therapy with divided doses of penicillin. Because of its safety and rapid cure penicillin is the drug of choice for the treatment of chronic gonorrheal vaginitis in children. One 100,000 unit dose of penicillin injected intramuscularly seems adequate in most cases. Hospitalization is not necessary.

EPIDURAL SPINAL ABSCESS

FRANCIS C. GRANT, M.D.
PHILADELPHIA

The consequences of an unrecognized purulent collection in the epidural space can be so devastating that further emphasis on the clinical syndrome accompanying this lesion has ample justification. Although over 200 cases are reported in the literature and recent reviews by Gasul and Jaffe,[1] Browder and Meyers [2] and Campbell [3] have drawn attention to this condition, nevertheless the high percentage of delayed diagnoses with resulting irreversible cord damage causing severe and permanent neurologic sequelae warrant a further report. The 14 cases on which this communication is based furnish no new nor striking clinical information. But the antecedent history and development of symptoms is so uniform that repetition is justified, if only to remind the profession that this condition does exist, to describe again its salient features and thereby, perhaps, help in early diagnosis and prompt operation. For unless realization is widespread among medical men that epidural infection can and not infrequently does follow infection in other parts of the body, valuable time is lost in performing laminectomy. In consequence, the spinal cord suffers irreparable damage.

The epidural space is formed by a separation at the foramen magnum of the layers of the dura as it passes down over the spinal cord. The outer layer forms the periosteum of the laminas and bodies of the vertebrae; the inner, the dura proper surrounding the cord. Anteriorly to the cord the two layers are closely approximated, but posteriorly the dura over the cord falls away from the laminas to form the epidural space containing the epidural fat with its many veins. Dandy [4] states that the spinal epidural space is present only dorsal to the nerve attachments. Ventral to the nerve the dura is everywhere closely applied to the bones of the vertebrae and their ligaments. Below the second sacral bony segment the epidural space surrounds the dura on all sides. Of greatest importance are the variations in the size of the epidural space. In the cervical region the space is only potential, there being but a few strands of fibrous tissue and almost no fat between the laminas and the dura. The epidural space really begins to appear at the seventh cervical vertebra and gradually deepens along the thoracic vertebrae, attaining a depth of about 0.5 to 0.75 cm. between the fourth and eighth dorsal vertebrae. The space tapers again and becomes shallow between the eleventh thoracic and second lumbar vertebrae. Over the remaining lumbar and the first and second sacral vertebrae the epidural space attains its greatest depth. Consequently an epidural abscess rarely is found above the fourth thoracic. The lower thoracic and lumbar areas, where the epidural space is largest and the veins in the epidural fat most numerous, are the common sites for infection.

Hematogenous infection is much the more common cause for epidural abscess. Many blood vessels run in the epidural fat and anastomose freely with those entering along the spinal nerves. Batson [5] has shown recently that the venous anastomosis reaching into this area is more extensive than hitherto suspected. The constant repetition in the case histories of local acute infection, usually a furuncle, preceding the epidural focus and the frequency with which the staphylococcus is the organism found in both areas seems convincing evidence that the blood stream has been involved. In the 88 cases from the literature analyzed by Browder and Meyers, 72 were apparently blood borne. The staphylococcus was commonly recovered, 59 of these 72 cases having been due to this organism.

An epidural spinal abscess may be acute, subacute or chronic. If free pus is found in the epidural space without granulation tissue on the dura, the abscess is considered acute; if both free pus and dural granulations are encountered, the abscess is subacute; whereas, if a solid extradural fibrous mass without definite macroscopic evidence of infection is discovered, the abscess is undoubtedly chronic.

An epidural abscess forms as the result of an adjacent infection spreading to the epidural space or by blood borne infection from a distant focus. Direct trauma, a bullet or stab wound or a retropharyngeal or posterior mediastinal abscess are all possible causes of direct infection. Campbell reports a case originating from a furuncle of the external chest wall and 15 cm. from the operative site. Pressure over this area caused pus to well up into the laminectomy wound. Infected pilonidal cysts (Campbell, Stammers [6]) have caused epidural infection. Hunt [7] and Browder and Meyers are of the opinion that osteomyelitis of the vertebra is a constant finding. They account for the frequently recorded tenderness over the spinous processes adjacent to the abscess on this basis. Stammers reports cases in which vertebral osteomyelitis was present

accompanying epidural abscess, but McNutt [8] describes 2 instances in which osteomyelitis of the vertebrae was diagnosed by roentgenographic studies without accompanying infection of the epidural space. In reading the operative notes of the reported cases of epidural infection, mention is made but rarely of osteomyelitis of the overlying spines and laminas, although not uncommonly it is stated that pus was encountered on separating the muscles from the spinous processes. Only occasionally is reference made to softening or other changes in the bone, although such changes may not have been sufficiently extensive to attract the attention of the operator.

An epidural abscess is almost always found posteriorly to the cord. Mixter,[9] Campbell, and Browder and Meyers report cases in which the abscess lay anteriorly. This was true in 1 of our cases. Infection immediately adjacent to the vertebral bodies, as a retropharyngeal or peritonsillar abscess, may track inward, involve the body of the vertebra and enter the epidural space anteriorly. But since in this region the dura is tightly adherent to the bodies of the vertebra, the abscess is always localized. The general infection of the epidural space which is so frequently encountered when the posterior region is involved never occurs when infection appears anterior to the dura. The symptoms are less fulminating, pain is rarely severe and diagnosis may be difficult.

TABLE 1.—*Source of Infection*

Of 88 cases	72 hematogenous
Of 72 cases	59 Staphylococcus aureus

Browder and Meyers in 1937 reviewed 210 cases, of which "156 may be classified as acute, 2 as subacute and 52 as chronic forms of the disease." As just stated, Browder and Meyers found 88 cases with sufficient data to warrant analysis. In this group were 71 cases described as acute, with 43 deaths and 28 recoveries, 2 subacute cases with 2 deaths and 15 chronic cases with 12 recoveries and 3 deaths.

A review of the literature [10] since 1937 shows a total of 55 cases, to which we add 14. Of these 69 cases 44 were acute. In this group 19 patients were operated on with complete recovery of all functions, 11 were operated on and survived the operation with little or no recovery from their paralysis, 13 succumbed following surgical intervention and 1 died without operation. In 6 subacute cases there were 4 recoveries following operation with complete return of function, 1 recovery without improvement in neurologic symptoms and 1 operative fatality. The chronic group numbered 19. Ten recovered completely following laminectomy, 2 survived operation without return of function and there were 2 immediate operative fatalities. In 35 of the 44 acute cases the history states that a furuncle or other acute superficial infection immediately preceded the onset of cord symptoms.

TABLE 2.—*Review of 88 Cases Before 1937*

	Died	Recovered	Mortality
Of 71 acute	43	28	60%
Of 2 subacute	2	..	100%
Of 15 chronic	3	12	20%

It would seem, therefore, that the attention called to this condition by the reviews referred to has lowered the operative mortality rate and, more important still, increased the percentage of patients who have completely recovered from their disabilities. Without question, early diagnosis and prompt operative intervention are essential to total recovery. The delay is commonly caused by lack of appreciation that acute infection can involve the epidural space and that immediate laminectomy is indicated.

The symptoms of an epidural infection appear with an almost monotonous regularity. A careful history will show that a previous infection has existed, usually a furuncle or other skin infection. Within a week or two the patient has pain, usually very severe, in the back or down the legs. A few days after the pain appears, numbness and finally paresis, passing on to complete paralysis, develop in the legs and extend upward rather rapidly. Loss of sphincter control may appear early and be complete. As the anesthesia and paralysis develop, the pain may become less pronounced. Physical examination reveals a sick patient, usually febrile and showing a leukocytosis. Neurologic studies indicate a cord lesion, more or less complete, depending on the time at which the patient is seen and the virulence of the infection. Palpation of the spinal column frequently reveals an area of acute tenderness corresponding with the upper level of sensory change. In some cases a slight edema and swelling of the spinal muscles may be present in this area.

TABLE 3.—*Review of 69 Cases Since 1937*

	Total	Died	Recovered	Mortality	Recovered Function
Acute	44	14	30	31%	19
Subacute	6	2	4	33%	4
Chronic	19	2	17	10%	15
Total	69	18	51	26%	38

Lumbar puncture will give extremely valuable information but must be done with caution. If an epidural infection is suspected, the needle should enter the epidural space and then be aspirated. The presence of pus confirms the diagnosis. It is essential, of course, to avoid penetrating the subarachnoid space through an epidural collection. However, if lumbar puncture

is carried out in a routine fashion a partial or complete block will be evident with increased protein, possibly xanthrochromia and a slight polymorphonuclear pleocytosis in the fluid. This evidence from the Queckenstedt test of a mass lesion within the vertebral canal eliminates the possibility that the apparent transverse myelitis is due to intrinsic cord disease. Operative intervention at the proper level indicated by the sensory change is urgently indicated. If laminectomy reveals pus, the wound should be packed open after adequate drainage has been assured. The sulfonamide derivatives may be used in powdered form in the wound as well as by mouth. Curiously enough, Reeves [11] in a recent paper reports the first case of acute epidural abscess in which they were employed. His patient recovered.

The cause for the transverse myelitis in the acute cases apparently is a degeneration in the spinal cord due not so much to pressure as to circulatory stagnation. The abscess is seemingly too widespread and diffuse to bring about destruction of the cord by direct pressure, and irreversible damage is too quickly produced to be due to this factor alone. Rather an obstruction of the venous plexuses of the epidural space, meninges, and in the cord itself occurs, due to irritative and inflammatory processes. A stagnation edema appears, causing distention of tissue spaces, and the adjacent neural fibers are affected by compression.

TABLE 4.—*History of Infection*

1. Severe pain in back
2. Painful spinous process
3. Neurologic signs progressive
4. Spinal block

A chronic epidural abscess is often indistinguishable from an extradural spinal cord lesion, both in the development of symptoms and grossly at operation. In many of the cases reported in the literature and in all of the 5 chronic cases in the present series the clinical diagnosis was presumably that of a fibrosarcoma. The majority of these chronic epidural granulomas invade the dura, and either sharp dissection is necessary to separate the dura from the tumor, or the tumor and the invaded dura must be removed in one mass. The prognosis not only for immediate operative recovery but also for ultimate return of function is much better in the chronic than in the acute cases. The slower development of compression symptoms and the absence of widespread interference with the blood supply of the cord and of virulent toxic material in the epidural space result in less serious damage to the neural structures.

In this small series of 14 cases 6 were acute, 3 subacute and 5 of the chronic type of abscess. All the patients were operated on. Of the 6 patients with acute abscess, 2 died following laminectomy and 4 recovered, 2 with serious neurologic sequelae. Two patients with acute epidural abscess recovered function completely as the result of a prompt decompression and drainage. All with subacute abscess survived operation and 2 had satisfactory restoration of function. Of the 5 with chronic abscess 1 died following operation and, of the 4 survivors, but 1 had complete return of power in the legs with adequate sphincteric control.

3400 Spruce Street.

11. Reeves, D. L.: Acute Metastatic Spinal Epidural Abscess: Report of Two Cases with Recovery Following Laminectomy, Arch. Surg. 41: 994-1003 (Oct.) 1940.

ABSTRACT OF DISCUSSION

DR. ADRIEN HENRI VERBRUGGHEN, Chicago: I have not seen a case of this kind since 1937, so it must be becoming a rarity around here. Two of the cases that I had were due to a cause which Dr. Grant did not mention. Both of them were due to attempts to include spinal anesthesia, evidently due to some infection of the skin or in the presence of infection somewhere in the deep tissues. One was an attempt to produce continuous extradural spinal anesthesia; the other was secondary to an ordinary straightforward spinal anesthetic. The prognosis, as Dr. Grant mentions, is quite poor; of the 6 patients with whom I have had some experience 2 died. They were all operated on. Two died following operation, 2 of them remained completely paraplegic following operation and 2 of them had some return of function with bladder control but weakness and spasticity in the legs. It seems likely that we shall see less and less of this condition and not more and more of it, for it seems to be one for which penicillin was invented. If it is recognized early, and possibly large doses of penicillin are given before paraplegia results, it may not be necessary to perform a laminectomy.

DR. A. W. ADSON, Rochester, Minn.: In reviewing the records of cases of pyogenic infection of the spinal extradural space at the Mayo Clinic, I found that we had operated in 12 such cases. The review consisted of an analysis of etiologic factors, symptoms and operative results. Our findings corroborate the observations made by Dr. Grant. Six of the patients were men and 6 were women. The patients were young adults, with one exception—a man of 60. In 4 cases the infection was the result of recurring osteomyelitis. In 2 cases it was due to a diffuse furunculosis; in 1 it was due to a large carbuncle on the neck. In 2 the lesion developed subsequent to a paranephric abscess, and in another case it followed an empyema and a mediastinal infection. In 1 case it developed following trauma to a lumbar vertebra and disk. In the twelfth case we were unable to determine the etiologic factor. The general symptoms were those of a chronic systemic pyemia. The temperature elevations were rarely more than a degree or two. The leukocyte count usually averaged 9,000 to 10,900 per cubic millimeter. The pus contained Staphylococcus aureus; however, it was sterile in 3 cases. In only 2 cases was there roentgenographic evidence of bony destruction. The characteristic local symptoms were those of a transverse myelitis without the signs of a diffuse meningitis. Spinal punctures were avoided. The progress of symptoms was fairly rapid; the symptoms developed within twenty-four to seventy-two hours. In only 3 of the 12 cases did a complete transverse myelitis develop. No recovery was obtained by drainage of the abscess in these 3 cases. Nine patients had partial paralysis. In some instances the motor loss was in excess of the sensory loss, and in others the reverse was true. The results of surgical drainage were successful in 5 cases since complete recovery of function occurred. In the remaining 4 cases only a partial recovery occurred. There were no surgical deaths. The patient with empyema died at home several months after operation. An early diagnosis is imperative, and surgical drainage should be instituted before the signs of a complete transverse myelitis have developed. If the extradural spinal abscess is drained without injury to the dura before extensive paralysis is present the prognosis is reasonably good.

DR. GEORGE B. HASSIN, Chicago: In 1 of our cases there was an abscess above the dorsal surface of the dura. There were no signs of pressure on or compression of the spinal cord. The size and configuration of the latter were preserved but the various tracts showed scattered areas of rarefaction. The dura underneath the abscess was thickened, hyperplastic and separated from the subjacent arachnoid by a widened subdural space. The ventral portion of the dura, in contrast, was normal. In addition the perineurial spaces—over the spinal roots—were obliterated. Because of the obliteration of these spaces, which was caused by adhesions between the roots and the subarachnoid spinal membrane, the flow of the cerebrospinal fluid from the subarachnoid space along the spinal roots was interfered with and the tissue fluids of the spinal cord therefore could not be discharged. They become stagnant, causing the rarefaction. The perineurial space obstruction and not the compression of the spinal cord—as assumed by the neurosurgeons and in general—is responsible for the clinical picture of an epidural abscess,

such as root pains, paraplegia and sensory and genitourinary disturbances. As emphasized by Dr. Grant, the clinical picture should be recognized as early as possible and the abscess removed, thus preventing the occurrence of the changes in the roots and spinal cord as demonstrated.

DR. FRANCIS C. GRANT, Philadelphia: I brought up the subject of epidural spinal abscess and have again described the clinical syndrome connected with this lesion in the hope that earlier recognition might follow. As Dr. Hassin has said, if these patients are permitted to become paraplegic the results following surgery are far from satisfactory. Dr. Verbrugghen suggests that the use of penicillin or the sulfonamide derivatives might avoid the necessity for operation. I am sure that he made this suggestion so that I could protest strenuously against it. Any delay in these cases is dangerous. Immediate operation is indicated as soon as the diagnosis is reached. To wait twenty-four to forty-eight hours to determine the effect of either or both of these drugs can easily result in permanent cord damage. The clinical picture of severe pain in the back, then sudden onset of signs of spinal cord involvement, plus a partial or complete block on Queckenstedt test, forms a triad of symptoms demanding immediate surgical exploration.

Clinical Notes, Suggestions and New Instruments

MALARIA AND THE RETURNING SOLDIER

S. B. OSGOOD, M.D., GRANTS PASS, ORE.
Health Officer, Josephine County Health Department

More than a year ago Coggeshall [1] pointed out the possibilities of the spread of malaria in wartime to civilians. As far as I can determine, the periodical literature for the past two years has contained very few references to the occurrence of malaria cases in new areas or an increase in prevalence of malaria in endemic areas since the war. Jeffries [2] reported 1 case of estivoautumnal malaria occurring in a merchant seaman who returned to Oregon. However, there had been no report of any secondary cases arising. My purpose in the present discussion is to report 2 cases of tertian malaria and the evidence from which I conclude that a returned soldier was the source:

CASE 1.—R. C., a white girl aged 12 years, a student, was seen in the office on Aug. 5, 1944 complaining of chills and fever of one week's duration. Since the child was obviously acutely ill (temperature 104.4 F. by mouth), she was referred to a private physician for further examination and treatment. In view of the history of chills and fever, it was thought advisable to secure a blood culture for undulant fever, together with thick and thin blood films for malaria. Her blood films were examined in my office, in the laboratory of the Josephine General Hospital and in the Oregon State Hygienic Laboratory. The presence of Plasmodium vivax in these films was confirmed independently by each laboratory. The cultures for undulant fever were subsequently reported negative. Quinine therapy was instituted by the attending physician the same day. The patient has remained free from chills and fever since that time. Epidemiologic investigation the following day revealed that the patient had felt perfectly well until July 30, at which time a sharp chill, followed by rise in temperature, occurred. The patient felt well and was able to be up and about on July 31 but was again taken with a severe chill about noon on August 1. Severe shaking chills had occurred again on the 3d and the 5th almost exactly forty-eight hours apart. The patient's household consisted of her mother, the grandparents, a sister and an infant cousin, all of whom were well and had been so for the preceding sixty days. A great-uncle (T. M.) had lived in a tent approximately 50 feet from the patient's house for more than two weeks immediately prior to the illness. Relatives volunteered the information that the uncle had been discharged from the United States Army in February 1944 with chronic malaria after having served in the South Pacific area from March 1942 to November 1943. Effort was made to get in touch with him, but his whereabouts were unknown as he was in another county looking for work.

The patient had lived in the same area of Josephine County for her entire life and had never left the county for even a short period. There had been other visitors in the household, but as far as could be determined no one else had been ill among the household or near neighbors. Neither had any cases of malaria been reported from this county for ten years,[3] with the exception of 2 exogenous cases whose sources were known, and the patients had never lived in the neighborhood.

The patient's residence was a one story frame building only partially completed, in which several of the window panes were missing and which was entirely unscreened. The house was located approximately 50 feet from the edge of Grave Creek. Mosquitoes were abundant in the residence of the patient at the time of the investigation on August 6. Mosquito specimens were collected from the residence of the patient. These were identified as Anopheles punctipennis and Culex tarsalis by Ernest C. Anderson, assistant entomologist, U. S. P. H. S., of Oregon State College.

CASE 2.—Mrs. E. A., aged 44, white, was seen in my office on Sept. 12, 1944 with a history of chills and fever since September 4. Questioning revealed that the chills and fever had occurred every other day since the onset and that the patient's residence was less than a quarter of a mile from that of patient 1. Blood films for malaria were taken and examined in my own laboratory, the laboratory of the Josephine General Hospital and the Oregon State Hygienic Laboratory, all of which reported the finding of Plasmodium vivax. The patient was referred to a private physician for treatment and was placed on quinine therapy. No further attacks of chills or fever have occurred since that time.

Epidemiologic investigation revealed that the household of Mrs. E. A. consisted of herself and her husband. Their home was located on the opposite side of Grave Creek approximately 400 feet downstream from the residence of patient 1. The residence was a one story frame building which had not yet been completed and in which many of the window panes were missing. It was entirely unscreened.

History revealed that the great-uncle, T. M., of the previous patient passed the house very frequently and that his home was well within flight range of anophelines. The patient had not been out of the county for several months and had had no visitors except those from the immediate neighborhood. Unfortunately, on the day of investigation of this case (September 13) the weather was rather cold and no mosquitoes could be found in the house. The patient and her husband said that the mosquitoes had been very numerous during the preceding months and agreed to collect specimens in the house at their earliest opportunity. On September 15 the husband brought in a collection of 7 specimens which were trapped in his house, and these were forwarded to Mr. Ernest C. Anderson, assistant entomologist, U. S. P. H. S., of Oregon State College, who reported that 6 of the 7 specimens were Anopheles maculipennis freeborni—the common malaria vector in Oregon.

After repeated efforts to locate the great-uncle of patient 1 he was finally seen at home on November 1. At this time he gave the history of serving in the South Pacific area from March 1942 to November 1943, having first developed clinical malaria in Townsville, Australia, in October 1943. He was treated intermittently for clinical attacks of the disease from that time until his discharge from the United States Army on Feb. 16, 1944 at McCaw General Hospital, Walla Walla, Wash.

Since his army discharge he had spent most of the time at the home of his mother on Grave Creek. This residence is

Through his alertness, Dr. M. E. Corthell of Grants Pass made possible the diagnosis of the first case within two hours. Dr. A. J. Fawcett of Glendale, Ore., confirmed the fact of preexisting malaria in the source case. Mr. Ernest C. Anderson of Oregon State College, Corvallis, Ore., identified the mosquitoes collected from the homes of the patients.

1. Coggeshall, L. T.: Malaria as a World Menace, J. A. M. A. 122: 8 (May 1) 1943.
2. Jeffries, B.: Wartime Malaria in Oregon, Northwest Med. 42: 285 (Oct.) 1943.
3. Official records of Josephine County Health Department, Grants Pass, Ore., further substantiated by search of communicable disease reports in the files of the Oregon State Board of Health

located on the north side of Grave Creek immediately opposite the residence of the second patient and approximately 400 feet downstream from the residence of the first patient.

During the latter part of July and first part of August he lived in a tent adjoining the residence of the first patient and was frequently bitten by mosquitoes. During this period he was living with a logging partner, C. C. I have been unable to locate this man, as he returned to Texas before the investigation revealed that he was a contact. However, I am informed by the husband of the second patient that C. C. suffered from chills and fever during the last part of his stay on Grave Creek.

Mr. T. M. states that he had several attacks of chills and fever during the summer of 1944 and was quickly relieved of one severe attack, which occurred on or about August 1, by the administration of quinine obtained from Dr. A. J. Fawcett of Glendale, Ore. Correspondence with Dr. Fawcett reveals that Mr. T. M. was seen by him on or about August 1, and the clinical diagnosis of malaria was made, although no blood films were taken.

Mr. T. M. states that he entered the United States Veterans Hospital in Portland, Ore., on or about Oct. 15, 1944 for a check-up leading to a disability claim, that he was told by the attending physician at the hospital that he had chronic malaria, and that he was given a quantity of atabrine. The patient was therefore requested to come to my office for further examination.

He was seen in my office on November 18, at which time blood films were taken and submitted to the Oregon State Hygienic Laboratory and to the laboratory of the Josephine General Hospital, as well as being examined in my office. All three laboratories found Plasmodium vivax present in abundance in the blood films on this date.

It is interesting to note that no cases of malaria occurred in the house of T. M.'s mother, where he spent most of the summer. It seems probable that this was due to the fact that his mother's house was completely screened.

CONCLUSION

Two proved cases of malaria, and possibly a third, were contracted from a returned soldier having chronic malaria. This occurred in a rural area which had been entirely free of this disease as far back as official medical records are available. The existence of anopheline vectors of malaria had not even been suspected prior to the occurrence of these cases. It would appear that careful mosquito surveys must be made in this and other districts where climatic conditions permit the existence of anopheline vectors, and that active mosquito control measures must be instituted if an increased incidence of malaria and its establishment in new endemic areas is to be prevented.

NEPHROSIS PROBABLY DUE TO EXCESSIVE USE OF STA-WAY INSECT REPELLENT

DAVID HOEHN, M.D., PALMER, ALASKA

A white boy aged 3 years was admitted to the hospital on Aug. 4, 1944, acutely ill with generalized edema. The swelling was most noticeable in the lower extremities, and the scrotum was about the size of a large grapefruit.

Urinalysis showed pus, albumin and no casts. A diagnosis of pyelonephritis or nephrosis was made on admission.

During the next few days the swelling decreased and the boy's general condition improved. However, a week later he had more edema, and three weeks after admission the edema became very pronounced again. At that time he was seen in consultation by Capt. H. A. Zimmerman, M. C., whose diagnosis was that of nephrosis.

I tried to elicit some information that might give a clue as to the source of the kidney damage. The child had always been well, and the fact that he was taken seriously ill so suddenly made me think that he might have ingested some toxic substance which caused the kidney damage. The father being a truck gardener, I thought the child might have eaten some of the poisons which are used to destroy insects. But the father insisted that he never kept any poisons around the place because of the child. I told the parents to keep thinking of something the child had done which might be harmful to him.

The mother received information from a friend that the insect repellent Sta-way had been banned for use in the Army because it might be harmful. She brought this information to me and admitted that they had used Sta-way very freely on the child's skin during the summer. The child was dressed in a play suit which covered only a small part of his body, and the exposed surface was liberally greased with the insect repellent. Early in the summer the boy developed a generalized skin rash, but the parents thought nothing of it and continued using the repellent in generous quantities. If the parents had discontinued the Sta-way when the rash appeared, probably no kidney damage would have resulted. The consulting physician and I both feel that this substance was the cause of nephrosis. I decided to investigate.

The physicians in a nearby army hospital were interested in this case and Lieut. Col. C. E. Albrecht, M. C., corresponded with Mr. H. H. Stage of the Bureau of Entomology and Plant Quarantine of the U. S. Department of Agriculture. He asked us to mail some Sta-way for toxic tests. Since the father had purchased two cases of Sta-way in the summer of 1943 there was still some of the substance available. It came from the same case that had been used on the little boy. To show how freely this substance was used, for a family of four only three bottles were left out of the two cases.

Tests done by the Committee on Medical Research and the Office of Scientific Research and Development showed that Sta-way is a severe kidney and liver poison to rabbits. Results of the test would indicate that Sta-way could be the cause of nephrosis in this child.

In September 1944 the child became much worse, and about the middle of the month his condition became extreme and it looked as though he would not live more than a few days. He was given plasma at the suggestion of Capt. H. T. Knoblock, M. C., and his condition improved. Four infusions of plasma (250 cc.) and two transfusions of whole blood were given. Although the edema did not clear up completely, we were not able to find any more patent veins to use and decided to abandon transfusing for a time. Possibly marrow puncture could have been used, but we were reluctant to do it, not having had any experience and not knowing how it would work in so small a patient.

For some time the boy was unable to void urine and great difficulty was experienced because of the long prepuce, which became very edematous and made it almost impossible to reach the urethra. On October 1 his condition improved so that we were able to do a circumcision, and this made his care considerably easier, although he was still quite edematous.

One point of interest was the formation of an ulcer in the boy's right inguinal area about October 15 which was very difficult to heal. Doubtless this was due to a thrombosed vessel. Onion vapor treatment was used with considerable success.

At the present time the child is in fairly good condition. The edema is almost all gone, he is fairly active and he eats well. Undoubtedly his life expectancy has been considerably shortened, and the danger of recurrence of the disease is imminent.

My purpose in this paper is not to give the treatment for nephrosis but rather to show the possibility of danger from the unrestricted use of this insect repellent, which has been very popular in Alaska. The Federal Food, Drug and Cosmetic Act does not cover insect repellents and therefore the Food and Drug Administration does not have any jurisdiction over this type of product. It seems that there should be some type of restriction so that indiscriminate use would be warned against. Proper legislation would enable the Food and Drug Administration to have administration over repellents so that such incidents would not be repeated. If the people were warned not to use the substance freely, and especially not to use it in the presence of a skin rash, I believe such unfortunate occurrences could be prevented.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following report. HOWARD A. CARTER, *Secretary.*

MEETING OF THE COUNCIL ON PHYSICAL MEDICINE

Abstract of Minutes

The twentieth annual meeting of the Council on Physical Medicine (formerly the Council on Physical Therapy) was held in Chicago on February 11 and 12. Those present were John S. Coulter, Chairman, Frank H. Krusen, Vice Chairman, Morris A. Bowie, Eben J. Carey, Anthony C. Cipollaro, A. U. Desjardins, W. E. Garrey, George Morris Piersol, H. B. Williams, Frank R. Ober and Howard A. Carter, Secretary.

Dr. John S. Coulter was reelected Chairman and Dr. Frank H. Krusen was elected Vice Chairman, replacing Dr. W. E. Garrey, who resigned at his own request.

A report on methods commonly used in artificial respiration, prepared by Dr. Bernard Ross, was presented for the Council's consideration. His report covers a five year survey of artificial respiration in emergency applications. The survey was supported by a grant in aid of research awarded by the Council. The report confirmed the Council's previous findings.

The Council decided to devote more time to the consideration of products containing radium and radon.

The assignment of frequency channels recommended by the Federal Communications Commission for use by diathermy apparatus was given consideration. The Council voted that in the interests of the public it desires to support the stand of the Federal Communications Commission and that it does not care to be in opposition to the federal agency which is responsible for this important decision.

War casualties have intensified the employment of occupational therapy. In view of the important problems currently arising in this field, the Council appointed a group of consultants. Those appointed were Dr. Winfred Overholser, Chairman, Dr. Raymond Allen, Col. Howard A. Rusk (MC), Dr. William Stroud and Dr. Francis Trudeau.

The Council also decided to revise the film on occupational therapy which will be made available for distribution or loan.

The Council was gratified with the progress being made by the Consultants on Audiometers and Hearing Aids. Drs. Gordon Berry and Moses H. Lurie were appointed to serve as members of this group of consultants.

A report by Dr. Thomas D. Allen for the Consultants on Ophthalmic Devices was accepted with enthusiasm and the Council realized that "orthoptics" might well be given more intensive consideration and study.

The Consultants on Contraceptives reported that they had had two meetings during the year and had defined their functions as follows:

1. To formulate minimum requirements or rules for the acceptance of contraceptive devices; and

2. To pass on evidence as to the effectiveness and dangers of such devices, making recommendations to the Council on Physical Medicine on which the Council may base its decision as to acceptance of such devices.

The Council voted to appoint a group of Consultants on Electroencephalography to assist in the investigation of electroencephalographs.

Considerable discussion was devoted to the role the Council will play in establishing a Section on Physical Medicine and a separate Board of Physical Medicine. At the present time physical medicine is regarded as coming under the American Board of Internal Medicine.

The Council voted to furnish gratuitously the booklet "Apparatus Accepted" to all junior students in schools of medicine. The third year is generally considered the term during which physical medicine is studied in medical colleges.

Considerable discussion was devoted to the responsibility of medical schools in teaching physical therapy and also to the entrance requirements for students studying to be physical therapy technicians. Teaching and entrance requirements of occupational therapy schools for technicians was also discussed. The revision of films on physical therapeutic subjects available through the Bureau of Exhibits was considered. The slides which have been prepared by the Council for teaching and lecturing purposes appear to be a good investment. A set of these slides may be loaned free of charge to qualified persons by writing to the Secretary, the borrower paying the express charges one way.

After due consideration, the Council reaffirmed its decision of several years' standing against the use in accepted advertising of the term "sunshine vitamin" when referring to vitamin D. The Council further reaffirmed its stand not to permit the word "Doctor" or its abbreviation as part of the name of an accepted product.

The Council adopted a list of devices which it considers as coming under its purview.

RADIAIRE (RAD-I-AIR) WITHDRAWAL OF ACCEPTANCE

Manufacturer: Tru Ad Company, 1019-1023 North Madison Avenue, Los Angeles.

The Radiaire ultraviolet disinfecting lamps were accepted and the report appeared in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, Dec. 11, 1943. These lamps were accepted for installation in hospital operating rooms, wards and nurseries. When considering the aforementioned lamps the Council had evidence that, under properly controlled conditions, the killing of air borne micro-organisms by ultraviolet rays may be used to supplement ordinary methods of disinfecting air for the prevention of cross infections in the aforementioned installations. Routine sanitary procedures in operating rooms, hospital wards and nurseries augmented by radiation from ultraviolet disinfecting lamps, the Council believes, will be an added precaution, but the Council does not regard these lamps a substitute for the orthodox disinfecting procedures which are accomplished by cleaning, scrubbing and the use of face masks and clean wearing apparel.

Since the acceptance of the Radiaire, the Tru Ad Company, a manufacturer of neon signs, organized a division of the parent firm and called it the Tru-Air Ultraviolet Products Company, 2151 Wilshire Boulevard, Los Angeles, California. This firm changed the name of the product to Rad-i-Air. Although there is a difference in spelling, phonetically the two sound alike.

A yellowish orange folder "Rad-i-Air Conditioner" has come to the attention of the Council. This folder contains claims that are unacceptable to the Council. According to the folder, Rad-i-Air is promoted for uses the Council does not accept, such as in factories, business offices, doctors' and dentists' offices, school rooms and home nurseries. As a matter of fact, the firm gives fifty-two recommended applications, beginning with "assembly halls" and ending with "waiting rooms," in which Rad-i-Air is promoted as valuable for preventing cross infection. In the list "hospitals" is the only installation the Council accepts. Throughout this folder there are unwarranted and misleading statements concerning the effectiveness of the lamps.

The Council is also in receipt of a purple pamphlet which the firm states has been withdrawn from circulation, although copies continue to come occasionally to the office of the secretary. This pamphlet contains unwarranted and misleading statements together with a list of industries in which the lamps are recommended for use, as for example the baking, meat, beverage, dairy and farming industries.

The Council does not accept ultraviolet lamps for disinfecting air in schools, waiting rooms, industrial plants, barracks, assembly halls or refrigerators. Evidence now available does not indicate that the incidence of colds can be reduced by the installation of ultraviolet lamps or by the irradiation of an enclosure occupied by people. Satisfactory evidence is not available to warrant acceptance of ultraviolet lamps by the Council for disinfecting solids.

In view of the unacceptable advertising the Council voted that the Rad-i-Air, formerly called Radiaire, manufactured by the Tru-Air Ultraviolet Products Company, a division of the Tru-Ad Company of Los Angeles, be withdrawn from the Council's list of accepted devices.

Council on Pharmacy and Chemistry

The Council has authorized publication of the following statement. AUSTIN SMITH, M.D., *Secretary.*

STATUS OF COSMETICS CONTAINING HORMONES

Today cosmetic preparations are advertised to the general public with the claim that they produce favorable changes in the human skin rather than merely alter its appearance. The advertising claims that the use of such cosmetics will remove wrinkles, make the skin more soft and pleasant to observe and change older looking persons to younger appearing, attractive and even glamorous people.

Some promoters incorporate hormones, such as estrogenic hormones. Others use impressive statements about lanolin, carbamide or some so-called special stimulating factor. The end result, regardless of the product and the sales approach, is the same—a useless outlay of considerable sums of money by purchasers who still believe in the development of "miracle" compounds that can be used safely with the assurance that their hopes for beauty and health will be fulfilled.

The public is now offered preparations containing ingredients as potent as hormones, without evaluation by any unbiased body. If the cosmetic preparations containing hormones will do all that is claimed for them, they must contain potent agents. Why, then, do none stand accepted by the Council on Pharmacy and Chemistry for inclusion in New and Nonofficial Remedies? Any compound promoted to affect the structure or function of a part of the body such as the skin should be carefully evaluated before it is released for general sale.

Much experimental work has been done on the cancer-producing properties of estrogenic substances. In susceptible animals the administration of estrogens has apparently produced carcinoma, but further observations are necessary to determine all possible effects of long continued use of such substances in the average human being. Some authorities believe that the injudicious use of estrogen-containing cosmetic preparations may permit sufficient absorption from the skin to upset normal body activities. For example, it has been argued that changes in menstrual rhythm may occur because of the absorbed estrogen affecting the activity of the pituitary gland.

Enormous sums of money are being spent to purchase hormone-containing preparations and yet many authorities in the field of endocrinology have stated time after time that there is no satisfactory evidence which would justify the use of hormone-containing cosmetics for their local effects on the skin. More than one authority has questioned the honesty of manufacturers when claims have been made that the promoted preparations would counteract age changes, wrinkles and skin blemishes.

Authorities in the field of endocrinology have stated that there is no published and acceptable evidence that age changes and wrinkling are consequences of estrogen deficiency or that estrogen therapy in women who are known to be deficient in ovarian secretion produces changes in the skin; nor is the deficiency of ovarian activity to be compared in importance with skin changes due to exposure, lack of care, malnutrition and many systemic diseases.

The physician who is asked to give advice to his patients concerning the use of cosmetic preparations containing hormones will ask: What are the local effects, the general effects, and what may follow long continued use? Satisfactory data to support the answers offered by the promoters have not been provided.

Frequently there has been suggested the need for carefully controlled studies when potentially active preparations are placed in commerce. Those who have kept in mind the importance of such studies have developed criteria for their guidance. However, when the scientific literature is searched for evidence concerning the studies made prior to the commercial distribution of cosmetics containing hormones and other substances, for that matter, the lack of convincing data is significant.

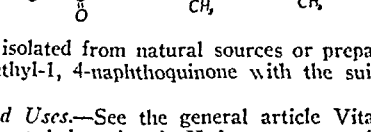
The prevention and treatment of disease and allied subjects are fields in which conjectural reasoning must give way to demonstrable facts. All new drugs should be studied in the laboratory and the clinic. The Council on Pharmacy and Chemistry in its consideration of new drugs asks for evidence of safety and for evidence to support the claims. Such evidence should be available for all who are urged to use a drug or other special preparation or to comment on its efficacy. Similarly, scientific facts concerning hormone-containing cosmetics should be generally available. Certainly the Council has not received satisfactory evidence on absorption, sensitivity, systemic effects, local beneficial effect, toxicity, relation of age, physical factors such as illness, and other factors. Until these and other studies have been completed, made public and found reproducible by unbiased investigators, there can be little honest reason to indulge in the promiscuous sale of hormone-containing cosmetics. Perhaps lack of such evidence is one of the reasons why promoters have not presented their preparations for Council consideration. Can financial gain be dominating humanitarian interests? If this is true, then there is no excuse for the widespread use of hormone-containing cosmetics.

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., *Secretary.*

SULFADIAZINE (See New and Nonofficial Remedies, 1944, p. 178).



The following dosage form has been accepted:

ELI LILLY & CO., INDIANAPOLIS

Tablets Sulfadiazine: 0.065 Gm. and 0.5 Gm.

VITAMIN K_1.—2-Methyl-3-Phytyl-1,4-Naphthoquinone.—$C_{31}H_{46}O_2$ (M. W. 450.68).

Vitamin K_1 has the following structural formula:

It may be isolated from natural sources or prepared by condensing 2-methyl-1, 4-naphthoquinone with the suitable phytyl derivative.

Actions and Uses.—See the general article Vitamin K. It has been suggested that vitamin K_1 has a more prolonged effect than menadione.

Dosage.—From 4 mg. to 10 mg. by mouth, with or without bile salts. Intravenous dose for adults may be as much as 10 mg. dispensed in dextrose solution. For newborn infants a dose of 0.25 mg. may be administered intravenously.

Tests and Standards.—

Vitamin K_1 occurs as a yellow, very viscous, nearly odorless liquid of specific gravity about 0.967 and refractive index of 1.5250 at 25° C. It is stable in air but decomposes in sunlight. It is insoluble in water; soluble in alcohol, benzene, chloroform, ether and vegetable oils.

Suspend one drop of vitamin K_1 in 10 cc. of methanol, add 0.5 cc. 6 N methanolic potassium hydroxide solution and shake. A deep purple color appears immediately, which slowly turns to reddish blue and finally to reddish brown.

Suspend about 0.5 Gm. of vitamin K_1 in 10 cc. of methanol, add a freshly prepared solution of 0.75 Gm. sodium hydrosulfite ($Na_2S_2O_4$) dissolved in 2 cc. of warm water and shake vigorously for a few minutes. The oily vitamin K_1 dissolves and a reddish purple color forms which soon disappears and the mixture becomes colorless. Dilute with water, extract twice with peroxide free ether and evaporate the ether extract under nitrogen or under vacuum; the white dihydro derivative obtained melts at 98.90° C. This dihydro derivative is readily oxidizable in air. Add one drop of vitamin K_1 to a mixture of 1 cc. of concentrated ammonium hydroxide and 1 cc. of ethanol and then add one drop of ethylcyanoacetate; no purple color is produced *(absence of menadione).* A solution of one part vitamin K_1 and 20 parts ethanol is neutral to litmus.

MERCK & CO., INC., RAHWAY, N. J.

Vitamin K_1: 1 Gm., 5 Gm. and 25 Gm. ampuls.

EXPERIMENTAL RHEUMATIC ENDOCARDITIS

In 1935 Schlesinger[1] found that deposits obtained by high speed centrifugation of pericardial fluids from cases of acute rheumatism contain minute bodies which in their size and shape resemble virus particles. Relatively pure suspensions of these particles were agglutinated by serums from acute rheumatic patients. They were not agglutinated by normal human serum or by the serum of patients suffering from nonrheumatic disease. Schlesinger did not challenge prevailing belief in the importance of hemolytic streptococci in acute rheumatic infections. He concluded that streptococcic infections lower normal resistance to the rheumatic cardiotropic virus or otherwise activate this virus.

Tests of the pathogenicity of the presumptive rheumatic virus are now reported by MacNeal and his associates[2] of New York Post-Graduate Medical School. In a typical experiment a specimen of pericardial fluid from a patient who had died of acute rheumatic carditis was passed through a Mandel filter. The bacteriologically sterile filtrate thus obtained was injected intravenously into a series of rabbits. The animals were killed at various intervals after the injection. Necropsies revealed scattered foci of inflammation in the myocardium, in one or more valves of the heart and in the pulmonary arterioles. The changes in the heart valves could be distinguished from those in experimental bacterial endocarditis by the absence of bacteria, the more diffuse dissemination of the lesions, their curious edematous verrucous character and particularly the accompanying hyperplastic and reparative activity of the endothelium and connective tissue. The experimental verrucous endocarditis thus produced was ordinarily not fatal.

The disease has been propagated in series through fifteen successive groups of rabbits by blood transfer. The causative agent has been propagated in a series in embryonated eggs. Allantoic fluid from such eggs injected intravenously produces even more pronounced lesions of the rabbit heart than the original pericardial exudate. This is presumably due to greater concentration of the virus. Numerous control injections have been made in rabbits injected intravenously with normal human blood, normal allantoic fluid, vaccinia virus, Theiler virus, influenza virus and similar substances. Such injection has not produced cardiac lesions identical with those following injection of the "rheumatic" virus.

MacNeal does not draw a conclusion from these data as to the probable relation of the virus to acute rheumatic disease. He merely reports his results as exemplifying the type of virus research that will be necessary before the presumably complex etiology of rheumatic infection can be determined.

SOME MALINGERERS COME HOME

Following World War I many a young man mentally disturbed by the trials and tribulations of military service appeared in the offices of physicians throughout the nation with symptoms that indicated loss of vision or of hearing or of locomotion or other activities of the body. The public dismissed these incidents in most cases with the trite appellation of "shell shock." This time they only shrug their shoulders and say "NP." One such soldier at the end of World War I, presumably blind, claimed to have recovered his sight through a single manipulation by an osteopath. Innumerable cases of loss of hearing recovered following something called the airplane treatment of deafness; they were taken 6,000 or 8,000 feet in the air; the airplane was permitted to make a sudden descent; when the passenger dismounted, he had recovered his hearing.

Apparently many people forget that there is such a thing as the power of suggestion which may strangely influence the sensations and activities of the human body. Many physicians lose sight of the diagnosis of hysterical paralysis. A recent instance concerns a young man who enlisted in the Marine Reserves late in 1943. After two or three months some hearing tests were made. When he missed some of the words he was sent to a physician. The physician told him that he would be totally deaf within one year. He was discharged from the Marine Reserves because of deafness. He was given attention by this physician over a considerable period and apparently recovered his hearing by the use of a bone conduction instrument strapped to his wrist. Indeed, he reported that he had been exhibited at a meeting of the New York Academy of Medicine, Section on Otolaryngology, as a remarkable case. Finally, he was tested recently with the apparatus known as the "lie detector," which indicated his ability

as a prevaricator. His hearing has been perfect ever since the experience with the lie detector.

The incident is here cited merely as another warning to the medical profession of the possible increase in malingering likely to appear with the discharge of many millions of men from military service.

ARTERIOSCLEROSIS

The vascular disorders grouped under the name of arteriosclerosis are becoming increasingly more important from the medical, social and economic point of view as a result of the growing proportion of older people in the population. In addition, the increasing concentration of the population in urban industrial areas has led to greater contact with factors which tend to promote this condition. Hueper [1] has published recently a series of papers reviewing this subject. As arteriosclerosis seemed to be a natural sequence of aging, senescence was early looked on as a causative factor in this condition, a view which, according to Heuper, was responsible for the stagnation in its investigation. This theory has been discarded by most investigators, since appreciable arteriosclerosis is not a constant phenomenon of old age. For any age group definite relation between the degree and distribution of senile vascular changes and arteriosclerotic changes has not been established. A toxin theory has also been proposed; in addition to bacterial toxins many substances of chemical nature, such as tyramine and digitalis, may exert direct toxic effects on the vascular walls.

A number of recent investigators have been concerned with the hydrostatic and dynamic factors of blood flow and their relation to the appearance of arteriosclerosis. The muscle tone of the blood vessels is an important factor in predisposing to arteriosclerosis. Many endogenous and exogenous factors which may influence vasotonia have been cited by investigators as playing some role in this disorder. Evidence has been published indicating that either a general or a local hypertonia, if of sufficient intensity, will cause changes of an arteriosclerotic nature. The hypotonia causes a reduction in blood supply and in pulse pressure, which will lead to an ischemic anoxemia of the blood vessel wall. On the other hand, hypertonia may lead to an ischemic anoxemia by compressing the vasa vasorum against the unyielding adventitia. This local anoxemia of the blood vessel wall is believed to be an important etiologic factor.

Another concept attributes arteriosclerosis to anoxemia which may be produced in the blood vessel wall by an aberration of the normal colloidal state of the blood. This disturbance causes an impairment of the exchange of oxygen and nutritive substances between the vessel wall and the blood by interposing either a film or a precipitate composed of colloids normally present in the blood stream, thus reducing the permeability of the vessel wall. This hypothesis has added interest since highly polymerized macromolecular carbohydrates have been suggested as plasma substitutes. After repeated doses these substances may cause plasma colloid disturbances which give rise to atheromatous changes in the blood vessel walls.

The wide distribution of arteriosclerosis coupled with its increasing incidence should give studies on this problem a high priority. Owing to its polyphasic nature it, like cancer, will probably require the cooperation of both the clinical and the laboratory investigators to elucidate the cause and point to measures of prevention.

Current Comment

EPIDEMIC MYALGIA, OR PLEURODYNIA

The records of this disease were reviewed editorially eleven years ago.[1] Since then a number of typical new outbreaks have been reported in this country and in Europe. The wide distribution of the disease in temperate climates is illustrated also by an outbreak in New Zealand.[2] The occurrence of the epidemics in the summer time, July and August especially, led de Rudder [3] to raise the question whether pleurodynia may not be a variant of epidemic poliomyelitis. The symptoms are however so different that poliomyelitis and pleurodynia must be regarded as etiologically distinct diseases. In reports of epidemics of pleurodynia, as in Illinois,[4] Massachusetts,[5] Missouri [6] and elsewhere, involving hundreds of cases, mostly in children, mention is not made of any simultaneous cases of poliomyelitis. This question as well as other problems of the nature of pleurodynia await the results of special investigations. So far there does not seem to have been made any biopsy or postmortem examinations in pleurodynia, and there seems to be no known record of any death from the disease. The clinical characteristics of epidemic pleurodynia were studied thoroughly by Locke and Farnsworth [5] in an explosive outbreak of 121 cases among the students of Williams College. The clinical type was constant: sudden onset with pain, fever and headache as the cardinal symptoms, the pain being the most characteristic and referable directly to the pleural covering of the diaphragm, hence in this instance at least the term epidemic pleurodynia seeming particularly appropriate. Clinically fibrinous pleuritis was demonstrated in 17 cases. Others have stressed tenderness, local swellings and firmness of hypogastric

and epigastric muscles, as indicated by the term epidemic myalgia. In the Williams College as well as other epidemics the infection appears to have been spread by contact, but exactly how is not known. A rather mild redness of the pharynx has been noted in certain cases. No doubt unrecognized cases are frequent as well as carriers.

REPORT OF NUTRITION FOUNDATION

The Nutrition Foundation, Inc., has now completed its third year of organization. The original membership of fifteen food manufacturers has increased to twenty-two, with a similar number of sustaining members and seven donors. The objective of the organization has been to support independent research and education in nutrition. Basic information valuable to the food industry and important in public health has been acquired. An impressive number of studies related to many aspects of nutrition are being supported in university centers. These projects cover such subjects as determination of the basic human food requirements, utilization of nutrients within the body, food needs under special conditions and the relationship of food to health. Other projects are assisting the military forces in the solution of nutritional problems directly related to the war. *Nutrition Reviews*, the monthly publication of the foundation, provides authentic information about nutrition, keeping the general worker abreast of significant developments in nutritional research. Foreign language editions are prepared for distribution in Central and South America. This cooperative effort of the food industry makes possible a systematic study of nutritional problems. The closer relationship existing between the research laboratory and the food industry will result in nutritional betterment of the population.

QUANTITATIVE CLINICAL MICROCHEMISTRY

As late as 1912 a reliable blood sugar method required 100 cc. of blood; a glucose tolerance test, run in duplicate under these conditions, would require 800 to 1,600 cc. of blood. Biochemists, among them Folin, Benedict and Van Slyke, developed micro methods through which clinical chemistry became a practical diagnostic tool. The demand for quantitative chemical studies then increased greatly in both number and types of determinations, with a concomitant increase in the amount of blood required. Furthermore, studies were now being undertaken on infants and children from which only small samples were obtainable. By refining the usual blood chemical methods it has been possible to develop ultra micro methods which require only 0.1 cc. of serum or plasma. Using this extremely small sample for each determination, Sobel [1] has outlined methods for the determination of calcium, phosphorus, nitrogen, urea and total base in the blood. In these methods the speed is usually increased and the technic is not highly complicated. The advantages of the ultra micro methods will be that a more adequate evaluation of the chemical status of a patient can be obtained with fewer samples and in a shorter time.

THE HISTOLOGIC ENVIRONMENT OF CANCER OF THE BREAST

Through the application of suitable histologic diagnostic technics accurate differentiation between cancerous and noncancerous lesions in the breast is possible, provided the training, the experience and the judgment of the pathologist are equal to the task. This optimistic statement cannot be made with regard to so-called precancerous lesions, in spite of diligent investigation by those who have so successfully solved the problem of the histologic recognition of cancer. We possess neither the data nor the experience necessary for biologic predictions in this field. Foote and Stewart [1] have tried to find out whether there is, in their own words, "a characteristic soil in which mammary carcinoma is apt to develop." In this investigation of the histologic environment in which cancer of the breast is found Foote and Stewart have relied chiefly on anatomic and statistical methods, but they have supplemented their anatomic observations by a study of the changes in the breasts of 9 women under treatment with estrogenic substance. The material used by these workers in their anatomic and statistical studies consisted of 300 breasts removed at operation for cancer and 200 specimens of noncancerous breast tissues obtained through either partial or total mastectomy. This material was compared in great detail, especial attention being paid to the occurrence in the cancerous and noncancerous breasts of histologic changes that have long been suspected of being intimately related to the genesis of cancer. These include atrophy, cysts, duct papilloma, blunt duct adenosis, apocrine alteration of the epithelium, sclerosing adenosis, periductal mastitis, estrogenic reaction and certain other epithelial proliferative changes in the mammary lobules. A critical analysis of the data accumulated from this comprehensive study failed to show with any degree of certainty either that cancer may be expected to occur when there exists in the breast a histologic environment characterized by the presence of any one, or any combination, of the various structural alterations just listed, or that the development of cancer in the breast is related in any way to estrogenic hormonal influences. It did not prove the absence of such relationships. The contribution lies in the essentially negative outcome of the attempt of these workers to determine what is and what is not a precancerous lesion in the breast. Pathologists will be better informed and more conservative in their recommendations, surgeons will be more hesitant to perform mutilating operations, and general practitioners and internists will be less frequently called on to make embarrassing explanations to patients and their families when the full significance of the findings of Foote and Stewart in this comprehensive study of cancerous and noncancerous breasts becomes widely appreciated. Studies such as this emphasize again the important fact that the two basic pathologic processes hyperplasia and neoplasia, seen so frequently in breasts, are not just simple histologic variants but instead are essentially different biologic processes, which can be differentiated and evaluated only in terms of biologic units of measurement.

MEDICINE AND THE WAR

ARMY

WHOLE MILK FOR PATIENTS ON HOSPITAL SHIPS

The War Department recently announced that a new method of quick-freezing whole milk is now making it possible to serve this beverage to wounded soldiers returning from overseas on Army hospital ships. This welcome and important addition to the diets on the hospital ships resulted from a series of researches carried out by the Veterinary Division of the Office of the Surgeon General.

Although the milk in some instances has been kept in the frozen state for three months, its taste is as fresh as if it had just come from the cow and the bacterial count is lower than that in the average milk supply of the average American home.

Approximately 30,000 pints of frozen whole milk is now being shipped monthly from Charleston and Boston, and additional large amounts from New York, New Orleans, San Francisco and Seattle.

While the milk is intended for the hospital ships, some of it, when the situation makes it possible, will be sent to overseas hospitals as well. Later it is expected to enlarge shipments for the hospitals. In addition, 400,000 pints is being shipped monthly to Alaska for the general use of American troops stationed there.

PROTECTION AGAINST SCRUB TYPHUS MITE

The War Department recently announced that the Office of the Quartermaster General, on recommendation of the Office of the Surgeon General, is replacing dimethyl phthalate with benzyl benzoate for use in clothing impregnation for protection of troops against the scrub typhus mite, so prevalent in the South Pacific. Clothing impregnated with benzyl benzoate will withstand more launderings before treatment is necessary than those impregnated with dimethyl phthalate. Clothing is dipped in an emulsion of 5 per cent benzyl benzoate in water. One treatment is effective for about two weeks.

1882d SERVICE UNIT RECEIVES AWARD

The 1882d Service Unit, Regional Hospital, Camp Maxey, Texas, was recently cited for superior performance of arduous duties in the care of injured persons resulting from a tornado at Antlers, Okla., April 12, 1945. The devotion to duty displayed by the hospital personnel and the numerous patients who volunteered their services, while coping with a serious situation created by this disaster, adds another achievement to the long list already attained by the Medical Department in war and peace.

ARMY AWARDS AND COMMENDATIONS

Colonel Crawford F. Sams

Col. Crawford F. Sams, chief of the planning branch, Supply Division, was recently awarded the United States of America Typhus Commission Medal. His citation declares that Colonel Sams "rendered distinguished service from January to August 1943 in connection with the work of the United States of America Typhus Commission. As chief surgeon at headquarters of the United States Army Forces in the Middle East, he aided the commission personally and administratively in establishing its first field headquarters at Cairo, Egypt. He assisted in the organization of the commission's early studies of typhus control in Egypt and put at the disposal of the commission essential facilities for all of its investigations. During the critical period of the initial activities of the commission in his theater of operations overseas, Colonel Sams contributed sound advice and guidance based on his expert knowledge of the problems to be solved. His assistance was a direct aid to the advancement of typhus control." Dr. Sams graduated from Washington University School of Medicine, St. Louis, in 1929 and has been in the service since July 1, 1930.

Lieutenant Colonel Robert E. Lyons Jr.

The Legion of Merit was recently awarded to Lieut. Col. Robert E. Lyons Jr., formerly of Shreveport, La., for "Services as chief of the medical record division, Eighth Air Force, from July 1942 to December 1943. He devised methods of compiling wound and injury data from sick and wounded reports and field medical records which resulted in a complete medical record of Eighth Air Force combat wounds. The major portions of the body receiving wounds were indicated by percentages, representing a total of all wounds. This important record revealed that a large proportion of serious and fatal battle wounds among air crews was caused by relatively low velocity missiles incurred in an area of the body that could be protected by armor. Based on this study, individual armor equipment for the protection of air crew members was developed and standardized throughout the Eighth Air Force. By constant review of medical records, he continually developed new methods of presenting and interpreting statistical data. He charted the geographic incidence and sources of injuries and diseases which resulted in an immediate intensification of the venereal disease program in all areas. He utilized the material in the revised care of flier report to prepare charts and data which contributed greatly to the reduction of frostbite and anoxia, thereby increasing the training level of combat crews before their shipment to the theater. He further conducted exhaustive research in the development of accurate attribution tables for air crews of heavy bombardment units by reviewing the combat history of hundreds of crew members in each crew position throughout their entire combat careers. After an enormous amount of work and research he completed the report which served as a temporary basis for computing replacement requirements and proved invaluable to the Army Air Forces material and services commands. By his untiring efforts, competent grasp of the situation and high devotion to study he contributed materially to the outstanding success of the aerial offensive against the enemy." Dr. Lyons graduated from Loyola University School of Medicine, Chicago, in 1937 and entered the service Oct. 24, 1940.

Lieutenant Colonel Douglas B. Kendrick Jr.

The Legion of Merit was recently awarded to Lieut. Col. Douglas B. Kendrick Jr., formerly of Washington, D. C. According to the citation, "while serving as chief of the division of surgical physiology, Army Medical School, Army Medical Center, Washington, D. C., from March 1, 1941 to Nov. 1, 1942 he distinguished himself by performing the duties of that office in an exceptionally meritorious manner by developing the program of the Army for obtaining adequate supplies of liquid and dried plasma, by developing the package for dried plasma, by developing the method for obtaining and processing liquid plasma and by establishing plasma centers for the zone of the interior, which has reflected great credit on him and on the military service." Dr. Kendrick graduated from Emory University School of Medicine, Atlanta, Ga., in 1931 and entered the service Dec. 7, 1936.

Major Bernard Rogoff

Major Bernard Rogoff, formerly of Ozone Park, N. Y., was recently awarded the Bronze Star Medal "for meritorious service in connection with military operations against an armed enemy at ——, Burma, from March 26, 1944 to April 8, 1944. During this thirteen day engagement Major Rogoff was commanding officer of the Medical Detachment of the 2d Battalion, —— Composite Unit. Major Rogoff displayed outstanding courage and judgment in the efficient handling of many

ous casualties at a time when evacuation was impossible and the aid station was subject to constant hostile fire. His calm courage, exhibited under most adverse circumstances, was inspiring to the wounded and to his own men and contributed largely to the superior performance of the detachment. Major Rogoff's conduct reflects great credit on himself and on the armed forces of the United States." Dr. Rogoff graduated from the University of Geneva, Switzerland, in 1936 and entered the service June 1, 1940.

Colonel Byron L. Steger

Col. Byron L. Steger, commanding officer of the 51st General Hospital in the Southwest Pacific, was recently awarded the Legion of Merit. The medal was given in recognition of his services from November 1942 to October 1943, when he was director of medical training at the Army Service Forces Unit Training Center, New Orleans. Dr. Steger graduated from Ohio State University College of Medicine, Columbus, in 1933 and entered the service Dec. 1, 1934.

Major Charles W. Yost

Major Charles W. Yost, formerly of Portland, Ore., was recently awarded the Bronze Star for meritorious service as Regimental Surgeon. The citation reads in part that "in the direction and supervision of medical service in combat and in the evacuation, care and treatment of the sick and wounded the leadership, judgment and devotion to duty displayed by Major Yost have been of superior quality." Dr. Yost graduated from the University of Cincinnati College of Medicine in 1938 and entered the service Dec. 9, 1940.

Captain George H. Lage

An Oak Leaf Cluster to the Purple Heart was recently awarded to Capt. George H. Lage, formerly of Portland, Ore., because of his second wound. Dr. Lage also holds the Silver Star and shares in the Presidential Citation given his unit for its services in the invasion of Normandy as well as the Oak Leaf Cluster for its part in the invasion of the Netherlands. Dr. Lage is now on limited duty with a hospital in England. He graduated from the University of Oregon Medical School, Portland, in 1939 and entered the service Sept. 22, 1942.

Captain Frank R. Hanrahan

Capt. Frank R. Hanrahan, formerly of Cleveland Heights, Ohio, was recently awarded the Bronze Star for "heroic achievement in connection with military operations against the enemy during his division's historic reduction of Metz." He directed operations of a battalion aid station in a highly distinguished manner, despite continuous exposure to enemy fire, and his heroic performance of duty was instrumental in saving many lives. Dr. Hanrahan graduated from Western Reserve University School of Medicine, Cleveland, in 1942 and entered the service July 16, 1943.

Colonel Norton Canfield

Col. Norton Canfield, formerly of New Haven, Conn., was recently awarded the Bronze Star for meritorious service. He is senior consultant in otolaryngology in the office of the chief surgeon at a base overseas. Dr. Canfield graduated from the University of Michigan Medical School, Ann Arbor, in 1929 and entered the service Dec. 1, 1942.

Captain Logan E. Jackson

Capt. Logan E. Jackson, formerly of Portland, Ore., was recently awarded the Bronze Star "for meritorious service in France. An outstanding example of Captain Jackson's leadership and cool judgment is the fact that he has not had a man lost through enemy action during the many combat engagements of this unit." He is commanding officer of a collecting company attached to the 35th Infantry Division and was with the 3d Army in its sweep through the Normandy beachhead and France and into Germany. Dr. Jackson graduated from the University of Oregon Medical School, Portland, in 1943 and entered the service Dec. 26, 1943.

NAVY

MARINE CORPSMAN INVENTS NEW TYPE STRETCHER

A new type stretcher, invented by Navy Chief Pharmacist's Mate John A. Gallegher and known as the Gallegher stretcher, is now being used daily over the tortuous hillside trails and down cliff-like embankments from which Marines are forced to root out encaved enemy machine gun and artillery nests. It is carried by from one to six men, can be used rigid or otherwise, and may be lowered by rope with the patient fully secure.

The stretcher weighs 4 pounds 6 ounces. It is transported in a small pack attached to the cartridge belt. Poles are inserted into its lengthwise seams if rigidity is preferred. Bamboo, usually abundant in the South Pacific, is used often. Three overlapping straps secure the patient in the lying position, while two other straps may be fastened around the thighs, similar to the way a parachute harness is applied, if the wounded man is to be lowered by line over an embankment.

Navy Chief Pharmacist's Mate John A. Gallegher, formerly of Brooklyn, is attached to Major Gen. Lemuel C. Shepherd's Sixth Marine Division. He has been in the service twelve years, eight of which were spent with the Marine Corps. He received a commendation for evacuating wounded from in front of the line of battle at Tulagi.

NAVY AWARDS AND COMMENDATIONS

Lieutenant Ralph W. Getty

Lieut. Ralph W. Getty, formerly of Syracuse, N. Y., was recently awarded the Bronze Star for his work during the Saipan and Tinian operations, where he was attached to the Fourth Marine Division. Dr. Getty graduated from Syracuse University College of Medicine in 1941 and entered the service July 14, 1942.

Lieutenant James S. Cate

The Bronze Star was recently awarded posthumously to Lieut. James S. Cate (DC), U.S.N.R., formerly of Baker, Ore. The citation accompanying the award read "For heroic service while attached to the 23d Marines, 4th Marine Division, during action against enemy Japanese forces on Saipan and Tinian Islands, Marianas Group, from June 15 to July 23, 1944. Voluntarily accompanying the regimental medical section in extremely hazardous operations, Lieutenant Cate repeatedly went to the aid of the wounded despite the peril of intense enemy artillery and mortar fire. With calm courage he skilfully treated and evacuated the stricken men, continuing his heroic efforts until he himself was mortally wounded. Lieutenant Cate's valiant conduct and cool disregard for his own personal safety were in keeping with the highest traditions of the United States Naval Service. He gallantly gave his life for his country."

Commodore William W. Hargrave

For serving as medical officer in command of the United States Naval Hospital, Pearl Harbor, Territory of Hawaii, and later as medical officer in command of the United States Naval Hospital, Aiea, Territory of Hawaii, Commodore William W. Hargrave, formerly of Philadelphia, was recently awarded the Legion of Merit, the citation reading "for exceptionally meritorious conduct in the performance of outstanding services to the government of the United States as medical officer in command of the United States Naval Hospital, Pearl Harbor, T. H., from Aug. 17, 1943 to July 3, 1944 and as medical officer in command of the United States Naval Hospital, Aiea, T. H., from July 4, 1944 to Feb. 9, 1945. A counsellor and director of rare understanding and broad vision, Commodore (then Captain) Hargrave exercised unfailing tact and wisdom in the administration of both hospitals and, applying his special knowledge with skill and judgment, created and maintained exceptionally high standards of professional service to the patients under his command. By his close personal

supervision, his sympathetic concern and genuine interest in the individual welfare and morale of personnel, Commodore Hargrave inspired and encouraged the rapid rehabilitation of patients essential to the successful prosecution of the war against Japan." Dr. Hargrave graduated from the Medical College of Virginia, Richmond, in 1912 and has been in the service since Nov. 2, 1914.

Commander Arthur Proctor Black

Comdr. Arthur P. Black, formerly of El Paso, Texas, was recently awarded the Bronze Star "for heroic service as senior medical officer in charge of a field hospital in northeastern China. Attached to the U. S. Naval Group, China, from Aug. 15, 1943 to Dec. 6, 1944, Commander Black was assigned the duty of organizing and establishing a field hospital in a forward area in the spring of 1944. Although handicapped by poor transportation facilities and the necessity of having most of the hospital equipment and fixtures made locally, he achieved exceptional success in carrying out this difficult project, effectively treating many Americans, some of them escaped from enemy concentration camps, and saving the lives of many wounded Chinese. His exceptional ingenuity, leadership and professional skill under difficult and, at times, adverse conditions were in keeping with the highest traditions of the United States Naval Service." Dr. Black graduated from Johns Hopkins University School of Medicine, Baltimore, in 1926 and entered the service June 10, 1941.

Commander Raymond R. Callaway

Comdr. Raymond R. Callaway, formerly of Birmingham, Ala., was recently awarded the Legion of Merit for his direction of five medical companies while under fire on Guam. The citation mentioned "exceptionally meritorious conduct in the performance of outstanding service . . . during the attack on Guam . . . from July 21 to Aug. 10, 1944. During the planning for the operations against the enemy on Guam he indoctrinated, trained and brought to a high state of efficiency and morale the personnel of the medical battalion. . . . He commanded, coordinated and supervised the activities of the five medical companies in such a manner as to assure prompt and efficient treatment of casualties. During the organized enemy attack on the division hospital on the morning of July 26, 1944 he organized the defense by hospital corps personnel and supervised the evacuation of casualties from the combat zone. All through this period he was frequently exposed to rifle, machine gun and mortar fire and without regard for his own safety contributed greatly to the defense of the hospital area. He displayed high professional skill and sound judgment as commanding officer of the five medical companies of the medical battalion and by his leadership and example contributed materially to the success of this campaign. . . ." Dr. Callaway graduated from the University of Illinois College of Medicine, Chicago, in 1928 and entered the service Dec. 1, 1941.

MISCELLANEOUS

FIGHT DISEASE IN GERMANY

American personnel, displaced persons and German prisoners of war are being safeguarded against communicable diseases and tuberculosis under a sanitation program directed by 5th Infantry Division medical officers in that part of the Ruhr controlled by the 5th.

Lieut. Col. Enos G. Walker, Detroit, division surgeon, and Lieut. Col. Howard H. Base, commanding officer of the 5th Medical Battalion, are directing the sanitation program for Allied personnel, the division's three displaced persons camps and seven Allied prisoner of war camps. By installation of an adequate diet and sufficient sanitation and medical facilities, the 5th Division team has cut the death rate 65 per cent a day in one prison camp.

About 75 persons are evacuated each day in the Hemer prison camp, Colonel Walker said. Of this number about 65 prisoners are suffering from dysentery and 6 from typhus. Small hospitals are being established in the vicinity of prison camps.

Guarding against the spread of typhus the division medical group is delousing thousands of displaced persons daily through use of DDT powder. Allied medical personnel are being assisted in prisoner of war camps by German medical units which have set up their own dispensary facilities, using American supplies and working under 5th Division supervision.

Buildings in the 5th's area of control are being sprayed with DDT powder to destroy breeding places of the typhus carrying louse. In addition to other precautions, men of the division are being educated to take precautions against being bitten by the lice because typhus inoculations are not 100 per cent preventive against the disease.

SELECTION OF FLYING PERSONNEL

Medical representatives of major airlines and aircraft manufacturers, members of the Airline Medical Directors Association, recently met at the Army Air Forces School of Aviation Medicine, Randolph Field, Texas, to study the methods that the Army Air Force has found most effective in the selection of flying personnel and the maintenance of their health.

Following an introductory address of Brig. Gen. Eugen G. Reinartz, commandant of the School of Aviation Medicine, individual members of the staff lectured on topics in which they specialize. The conference was held to aid the civilian doctors in preparing for the increasingly important role which they will play in postwar aviation. The problem of the "combat returnee and his place in postwar aviation" was one of the major topics of the conference.

MEDICAL AND HEALTH EXPERTS SENT TO CHINA

Herbert H. Lehman, Director General of the United Nations Relief and Rehabilitation Administration, recently announced that arrangements have been completed to send thirty medical and health experts to China to train personnel in medical centers to be established by the Chinese government. UNRRA will provide the essential medical supplies to equip the training centers. Shipment of these supplies has already started. It is estimated that within the coming months some 90,000 pounds of medical equipment will be sent to China.

The Chinese government plans to establish training centers in Chungking and Chengtu early this summer and later in Kweiyang. When Nanking and Peiping are liberated from Japanese control, other centers will be established in these cities. Short intensive courses averaging from six to eighteen months will be given to people recruited in China by the Chinese government. Refresher courses for medical practitioners, public health courses for recently graduated doctors and nurses who have not had public health experience, technical courses for partially qualified doctors and nurses and training courses for attendants, nurses and midwives will be given.

One of China's most serious needs is for skilled medical and technical personnel, and provision of foreign experts is part of the relief and rehabilitation program for China. Even before the Japanese invasion, China's public health services were inadequate for her population, and there was a shortage of doctors and nurses, medicines and hospital equipment. Now after eight years of war it is estimated that there is only 1 doctor for every 40,000 persons in China and 1 hospital bed for every 10,000 persons. War action has wrecked sewage disposal plants and contaminated water supplies. Up to 40 per cent of the hospitals in China have been destroyed or looted. The danger to national health will be even greater when the millions of Chinese who have been driven from their homes start their return. It has been estimated that China will need to train roughly 35,000 technicians in the next four years to administer her medical relief program.

For this program UNRRA is now recruiting medical experts in the United States, Great Britain, Australia and Canada. The recruits include surgeons, physicians, dentists, nurses, sanitary engineers, hospital and public health administrators and other specialists of various kinds. First to be sent to China will be the men with general medical experience. The specialists will follow later after the training programs are set up.

June 11, 1945.

Veterans Administration Probe Continues Despite Bradley Appointment

Investigation of the Veterans Administration will continue despite appointment of Gen. Omar N. Bradley to replace Brig. Gen. Frank T. Hines, who is to be given another assignment by President Truman. Chairman John E. Rankin of the House Committee on World War Veterans Legislation said that the change in chiefs would not affect the inquiry into the agency prompted by allegations of mismanagement of hospital and medical facilities.

Inadequate Hospitalization Found by Veterans of Foreign Wars

In its findings on conditions in Veterans Administration hospitals, to be released tomorrow, the Veterans of Foreign Wars reports that inadequate hospitalization for discharged veterans were found in 47 per cent of the hospital facilities operated by the Veterans Administration. Its survey, like the legion investigation, was conducted at the invitation of Brigadier General Hines. "We find grave conditions that must be corrected immediately," said Joseph M. Stack of Pittsburgh, Senior Vice Commander in Chief of the Veterans of Foreign Wars. "As we anticipated, the report underlines the shocking need for construction of a large number of new facilities and the desperate shortage of trained medical and service personnel. Management of the hospitals, both in the Veterans Administration central office and in the field, is subject to considerable, apparently justified, criticism. Unconfirmed allegations of abuse and mistreatment of veteran patients dot the individual state reports. But, while our overall survey discloses singularly few substantiated cases of mistreatment, there are too many instances of alleged and physical abuse cited for the Veterans of Foreign Wars not to demand an immediate sympathetic investigation of every charge by an impartial, authoritative body." The organization advocated an "undercover" probe, assuring immunity to each complainant.

Reorganization of Veterans Medical Division Urged

The entire Veterans Administration medical division should be reorganized and a medical man of the highest professional caliber should be appointed to direct hospitalization, treatment and care, the American Legion will recommend tomorrow to the House committee investigating the Veterans Administration. In a dual report prepared for release on June 12 the legion proposed (1) a list of eleven recommendations based on the results of a hospital and medical survey ordered by National Commander Edward N. Scheiberling in the nation's ninety-seven veterans' facilities and (2) a ten point administrative program calling for an administrator and six instead of three assistant administrators and also decentralization of much detail to eliminate red tape. "Hospital treatment and care should be at the same high level as that in the famous Mayo Clinic and Johns Hopkins Hospital," the report stated. The legion claims that veterans' hospitals are suffering from lack of medical personnel, red tape, staff dissension at some points, overcrowding and such low pay scales that staff morale is adversely affected. In some instances there is urgent need for latest scientific equipment. The legion recommended that the outstanding medical man to be assistant administrator or to have equal status should head the medical, surgical, clinical, dental, hospital and domiciliary services.

Veterans Administration Official Denies Charges

Magazine articles by Albert Q. Maisel criticizing treatment given ex-servicemen in the Veterans Administration were branded by Director John H. Baird of Veterans' Neuro-Psychiatric Hospitals as "distortions of the truth, half-truths and malicious falsehoods" during his testimony before the House Veterans Committee. "Mr. Maisel's articles," he said, "should be entitled 'Third Rate Lying and Slander for Money and Undisclosed Purposes' instead of 'Third Rate Medicine for First Rate Men.'" He further told the committee "Do not understand that I am contending that the care and treatment of our patients is all that we desire. Progressive medicine calls for continuous change and improvement. What I am telling you is that we are not practicing third rate medicine." He further stated that he was "not entirely satisfied" with the doctors under his control. He claimed that Civil Service standards are too loose to permit him to hire the type of physicians he required and he urged the committee to approve the pending bill to take Veterans Administration medical divisions out of the Civil Service System.

Approval of Permanent Postwar Scientific Research

A permanent postwar program of scientific research and development has been appoved by the House Military Affairs Committee. It authorized an annual expenditure of $8,000,000 for work to be conducted by the National Academy of Sciences through a research board made up of civilians of outstanding accomplishments" and Army and Navy representatives. President Truman has given War Mobilization Director Fred M. Vinson responsibility for reviewing scientific and technical information so that information which has been restricted for security reasons can be given to the public. The idea behind the executive order is to release details of scientific and technical progress developed during the war by the government. The Navy Department reports that it has formed a new Office of Research and Inventions to develop weapons and battle technics for use in the event of another war. The new office mérges the Naval Research Laboratory, the Special Devices Division of the Bureau of Aeronautics, the Office of Research and Development and the Office of Patents and Inventions. Navy Secretary James V. Forrestal will have direct supervision, while Rear Adm. Harold Bowen, known for his work with radar, will head the new office. The War Production Board also reveals that its Office of Production Research and Development has participated and cooperated in developing methods for increasing domestic production of quinidine and in developing superior processes for manufacture of DDT, and also helped to create a successful rubberless adhesive, using non-critical materials.

President Warns That Chemicals Should Remain on Critical List

In his outline of the war situation President Truman warned that certain chemicals, along with food, clothing, petroleum products and lumber, will remain on the critical list until the defeat of Japan. They are among a number of items, he said, in which there will be little lessening of demand for an indefinite period.

Capital Notes

Edward D. McKim, chief administrative assistant to President Truman, has denied that "politics" influenced the recent announcement that a new veterans' hospital would be constructed in eastern Montana.

An annual life insurance fund to be devoted to promotion of medical research was announced here by M. Albert Linton.

chairman of the joint Medical Research Committee of the American Life Convention and the Life Insurance Association of America. Half a million dollars is expected to be the amount of the fund available each year. The exact amount will depend on the number of companies accepting the invitation to participate.

Sanitation of merchant ships will be handled under a unified engineering and inspection program announced by the United States Public Health Service and the War Shipping Administration.

National Rehabilitation Week, proclaimed by President Truman, is being held to direct attention to the plight of the physically handicapped.

The War Production Board announces that the production period during which nurses' uniforms may be manufactured has been extended ninety days, or until the end of September.

Postwar Medical Service

MINUTES OF MEETING OF MAY 12

The meeting of the Committee on Postwar Medical Service was called to order by the Chairman, Dr. Ernest E. Irons, at 10:04 a. m., Saturday, May 12, in the Board of Trustees Room of the American Medical Association Building in Chicago

There were present Dr. Irvin Abell, Dr. Paul C. Barton, Lieut. Col. Robert D. Bickel, Dr. Walter L. Bierring, Dr. Paul C. Bucy, Dr. F. F. Borzell, Dr. C. W. Camalier, Capt. C. W. Carr, Dr. Frederick A. Coller, Mr. Graham L. Davis, Dr. Morris Fishbein, Dr. Evarts A. Graham, Dr. E. L. Henderson, Mr. Thomas A. Hendricks, Dr. W. W. Herrick, Dr. Ernest E. Irons, Dr. Victor Johnson, Dr. Edwin P. Jordan, Lieut. Col. H. C. Lueth, Dr. James M. Mason, Col. Hugo Mella, Col. F. V. Meriwether, Dr. James E. Paullin, Brig. Gen. Fred W. Rankin, Rev. A. M. Schwitalla, S.J., Dr. R. L. Sensenich, Dr. H. H. Shoulders, Dr. LeRoy H. Sloan, Mr. Barry C. Smith, Dr. Olin West, Major Richard J. White, Dr. R. C. Williams and Dr. Fred C. Zapffe.

Approval of Minutes.—The Chairman presented the minutes of the meeting of the Committee on Postwar Medical Service held on March 17, 1945 as they had been circulated and stated that a correction in the wording of his remarks had been submitted by Col. G. F. Gessner, that copies of the minutes containing this correction were available to the members and that the correction had also been incorporated in the printed minutes which appeared in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION for May 12. The minutes as circulated, with the correction mentioned, were approved.

Membership.—It was announced by the Chairman that Lieut. Col. Gerard F. Gessner, who has attended meetings of the Committee as a representative of the Surgeon General's Office of the War Department, has been assigned to other duties, and that Lieut. Col. Harold C. Lueth, formerly liaison officer between the Office of the Surgeon General and the American Medical Association, has been designated to take Colonel Gessner's place. The Chairman also announced that Capt. C. W. Carr of the Great Lakes Naval Training Station was in attendance at the present meeting to represent the Bureau of Medicine and Surgery of the Navy in place of Capt. William E. Eaton, the regular representative; that Dr. Paul C. Bucy was again in attendance to represent the Advisory Board for Medical Specialties, and that Dr. Paul C. Barton, Executive Officer of the Procurement and Assignment Service for Physicians, Dentists and Veterinarians, represented that service in the absence of Miss Mary E. Switzer, who was unable to be present.

Further Report on Questionnaires Sent to Medical Officers.—Lieut. Col. H. C. Lueth presented the following brief report supplementing the report given at the previous meeting:

> The section of the analysis of the questionnaires returned by medical officers dealing with economics will be presented to the Editor of THE JOURNAL. (It appears on page 528 of this issue.) The matter of most importance in this section is the question of the median monthly salary. It was asked in the questionnaire how much money medical officers would desire if they were to be on a full time paid monthly basis. The median salary desired is $583 a month. The different graduation groups show a surprisingly small variation. An even smaller variation occurs among men from the smaller communities.
>
> Perhaps the most interesting feature is the problem of whether the medical officers wish to enter group or private practice. The analysis shows that the majority wish to go into private practice by themselves or in a group. The greatest majority want to practice in an individual capacity.

Colonel Lueth's summary was received and publication of the full report authorized.

Request of American College of Hospital Administrators.—The Chairman presented a letter from the American College of Hospital Administrators in which it was stated that that organization is conducting a survey of officers in the Medical Administrative Corps of the Army to determine their interest in hospital administration as a career on returning from service and in which also the request was made that pertinent information, including names and addresses contained in the questionnaires of the Committee on Postwar Medical Service, be made available to the American College of Hospital Administrators.

Mr. Graham L. Davis stated that the College of Hospital Administrators and the American Hospital Association are working with several universities to establish courses of training, at the graduate level, in hospital administration; that it is desired to find out how many medical officers would be interested in going into hospital administration when demobilized, and that it had been thought the questionnaires would be an excellent source for such information. Colonel Lueth said that unfortunately the records compiled from the returned questionnaires are not on a name basis and that it is not known who wishes certain courses but only how many. He suggested that it might be well to get in touch with the various separation centers through which every man to be released from service must pass. Dr. Paul C. Barton stated that the Procurement and Assignment Service sends a questionnaire to every man under its purview who is leaving active duty, that about 50 per cent are returned and that if any of the men should say anything about hospital administration the Procurement and Assignment Service would let them know about this opportunity.

Some members of the Committee thought that to furnish the information requested might be interpreted as violative of confidences, and it was the final opinion of the Committee that it would be inadvisable to grant the request of the American College of Hospital Administrators. A motion was adopted approving the reply of the Chairman, in which it had been stated that the overall values for medical officers interested in hospital administration could be obtained from the recently published analysis of the returned questionnaires.

Request from Publisher of "Industrial Medicine."—The Chairman presented a communication from the publisher of *Industrial Medicine*, who wishes to reprint in that periodical Colonel Lueth's report on "The Medical Officer and Future Industrial Practice," which appeared in THE JOURNAL, May 12. It was the opinion of the Chairman and of the Committee that this was a matter for decision by the Editor of THE JOURNAL.

Further Report on Educational Internship and Residency Opportunities for Medical Officers.—Dr. Victor Johnson presented the following report:

> The Council on Medical Education and Hospitals has completed an analysis of the facilities for advanced training of veterans requiring expansion as well as the degree of expansion required in each field to meet the demands indicated by the questionnaires returned from medical officers.

This report will be published in detail shortly. The areas in most acute need are in surgery and its subspecialties, where nearly 1,600 new residencies will be required, and in medicine and subspecialties, where nearly 1,100 new residencies will be required. Large numbers of places will be needed in rotating internships and in obstetrics and gynecology.

Reports from hospitals are continuing to come in and indicate a fair likelihood that the expansion needs will be met if all concerned continue as vigorously as they have in the past in planning for the postwar period. The Council is now engaged in following up the original circular to obtain information from a considerable number of hospitals which have not replied. It is anticipated that a list of available residencies for the postwar period will be incorporated into the regular list of such house officerships published annually by the Council in the Educational Number, which will appear this year early in September.

In review and refresher short courses it is evident that the most acute need for expansion lies in the field of courses of three to six months' duration. There appear to be available now a sufficient number of courses of shorter duration, especially those of a month or less.

The Bureau of Information and the Council on Medical Education and Hospitals are cooperating in a reporting system from hospitals which makes available at frequent intervals information concerning vacancies in house officerships. This system will supply the relatively few medical officers who return within the next few months with the information they desire until the complete published lists can be produced.

In addition to the plans made by hospitals and medical schools, several of the state medical societies are also planning to assist in the educational program after the war, partly by contributing to teaching programs in which individual members are involved, partly by offering short courses under the auspices of the state medical society and partly by establishing funds to supplement other stipends which might be available to the returning physician during the training period. A survey is being made of all state medical societies requesting the details of such programs as may be contemplated.

Dr. Johnson's statement was received as a continuation report.

Dr. W. W. Herrick informed the Committee concerning a tentative plan of the New York Academy of Medicine to organize courses in New York City that will not be under university management, and the Chairman said that he thought similar procedures were being taken in Chicago and no doubt in many other places. Dr. Fred C. Zapffe stated that, as Secretary of the Association of American Medical Colleges, he had sent out a number of memoranda to medical schools about refresher courses and had received replies from about a dozen schools, a number of which maintained that nothing could be done until members of the faculties now absent in war service had returned; others are working on plans. He was sure that the medical schools will be ready. In reply to a question from Dr. LeRoy H. Sloan as to what is being done for the men now being discharged, Dr. Johnson stated that this matter is being handled through the Bureau of Information and asserted that there is no difficulty at all just now, since the hospitals are short of house officers and the Procurement and Assignment Service has declared that discharged medical officers accepted as house officers by hospitals will not be included in the hospitals' quotas. It was brought out in the discussion that many hospitals did not seem to be informed of this decision of the Procurement and Assignment Service, so that when some of the discharged men have applied for places they have been told that the hospitals were bound by the Procurement and Assignment Service and could not extend their facilities or their residencies, which, under the quotas, were filled up for two or three years to come. Dr. Barton stated that announcements concerning the decision of the Procurement and Assignment Service had been sent out more than once but that he would circularize all the hospitals again at the earliest possible time. Father Schwitalla mentioned that the Veterans Administration has figures on the number of men who are now in schools and hospitals under the G. I. Bill of Rights, that this information could be obtained easily and that hospitals are now taking in men on a nonquota basis.

Report on Bureau of Information.—Dr. Olin West informed the Committee that the Bureau of Information is not receiving as promptly as it had hoped the master sheets that contain information that it was desired to have checked in the individual states. He thought the chief reason for this, however, was that the state society offices were operating with depleted personnel. He stated that the Bureau of Information intends to act in strict, cordial and persistent cooperation with the state and county medical societies. The returns that have come in from the state and county medical societies are for the most part extremely informative. Dr. West deplored the fact that the state records, the records of the Bureau of Information and the Army records are not altogether in agreement. He reported that a number of inquiries already had been received from medical officers who have completed their terms of military service and wish to secure information that will enable them to move into a location at once. They are interested in communities that are at present short of physicians. Dr. West stated "We want to guard as fully as we can against the filling of places of men who expect to return to their own homes; we don't want to put others in their places." Some of the states are developing and wish to operate their own plans, and he knew of no reason why they should not do so and also cooperate with the Bureau of Information. He doubted that the machinery was as yet fully set up in the states. It is the plan of the Bureau of Information to refer to the states the men who are looking for locations. The collection of pertinent information will proceed and in due time the Bureau will be in position to be of great help. Dr. West stated that, if the members of the Committee wished to have more detailed information concerning the Bureau of Information, Lieut. Col. R. D. Bickel, liaison officer, would be glad to supply it.

Dr. Barton informed the Committee that the Procurement and Assignment Service has for some time been trying to do something quite similar, that with respect to the discrepancies in the records the Procurement and Assignment Service has some fine field workers who do nothing but check the lists and that theoretically the lists which the Bureau of Information obtains from the local Procurement and Assignment workers when checked with the information available at American Medical Association headquarters should bring the records into agreement. Dr. Barton mentioned two points in connection with the program of the Bureau of Information, the first being the policy concerning men over 65 years of age. He thought that the majority of these older men are located in communities to which younger men will never be attracted and that to leave the former out of the picture is to cause distortion. His second point was that he was in agreement with Dr. West's contention that the practices of men now in service should be saved for them, but he wondered if in adhering strictly to that procedure the field was not left open for less professional practitioners. Dr. West then asserted that with respect to sending men into areas where physicians are needed the plan was to let the states settle that, that no pressure will be put on any community or state and that the whole plan is to be helpful to the men themselves.

Dr. James E. Paullin pointed out that the phase of the Committee's plans that is being carried on through the Bureau of Information can best be done ultimately at a state level; state organizations know the needs in a particular state; the redistribution of physicians in rural areas is important; a letter might be sent to state organizations stating the purposes of the Committee on Postwar Medical Service, particularly in the matter of location of physicians in needy areas.

Report of Subcommittee to Draw Up Recommendations to the Governors of the States Concerning the G. I. Bill of Rights.—Dr. H. H. Shoulders, chairman of the subcommittee, reported as follows: The letter that was prepared by the subcommittee along the lines agreed on at the last meeting of the Committee on Postwar Medical Service was incorporated in the minutes of that meeting and published as a part of the minutes in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION for May 12. The letter was sent to the governors of each of the forty-eight states, to the president of the Board of Commissioners of the District of Columbia and to each territorial governor with the exception of the Virgin Islands and the Philippines. At the same time a copy of the "Governors Letter" was forwarded to the secretary and to the president of each constituent state and territorial medical association. Replies have so far been received from thirty-five governors and appear to be entirely favorable and cordial.

It was suggested by several present that follow-up letters should be sent to the state medical society secretaries, and Dr. Shoulders thought the governors might be asked to supply the committee with lists of those who are functioning as accreditors. No action was taken.

The report was received and the subcommittee continued.

Report of Subcommittee on Enrolment of Medical Students.—The Chairman announced that Dr. Victor Johnson would serve as chairman of the Subcommittee on Enrolment of Medical Students, and Dr. Johnson presented the following report:

There has been considerable delay in consideration of the Ellender bill by the Senate Committee on Military Affairs This bill was introduced late in February and seeks to correct the present policies and regulations which will either reduce medical school freshman enrolments materially in 1945 and drastically in 1946 or result in the admission of inferior applicants by some schools The delay was caused by failure of the Army, the Navy and the Selective Service System to communicate with the Senate committee expressing their views on the bill.

However, hearings were finally conducted on May 1. The Army, the Navy and the Selective Service System oppose the bill, contending that deferment of the few thousands involved would seriously hamper the war effort The measure was called unnecessary, since it was claimed that adequate numbers would be available for these classes without deferments Medical education was represented at the hearings by Dr Walter Bloedorn of the executive council of the Association of American Medical Colleges and Drs Harvey Stone and Victor Johnson of the Council on Medical Education and Hospitals of the American Medical Association Dr Johnson presented a joint statement over the signatures of Dr Fred C Zapffe and himself and in addition answered numerous questions by the senators Dr Stone reinforced and supplemented the contentions of the joint statement

As nearly as could be judged from the attitude of the senators, there appears to be considerable doubt that favorable consideration will be given the bill This is particularly true because of the strength of the opposition and not because of the individual opinions of the senators, who seemed impressed by the information provided them The hearings have been published, and it is planned that the committee will consider recommendations on this measure on Tuesday, May 15. Should this measure fail, attempts should again be made through adjustment of the regulations in the light of the altered military situation

Dr. Zapffe stated that he had received a telephone call from Washington the day before to the effect that the Ellender bill is unlikely to receive favorable action. A lengthy discussion ensued, during which Dr. Herrick stated that the New York Academy of Medicine is to have a meeting very soon at which this matter will be taken up, and Father Schwitalla read paragraphs from the report of his Subcommittee on Graduate Education of Physician Veterans, which he later presented in full.

Dr. C W. Camalier said that the American Dental Association is much interested and that the 1945 classes in dentistry were affected After further discussion Dr. Johnson stated that there is no intention of quitting now but that every opportunity will be taken to get some satisfactory adjustment

The Committee assented unanimously to the Chairman's appointment of Dr. Evarts A. Graham as an additional member of the Subcommittee on Enrolment of Medical Students.

It was Dr. Fishbein's opinion, in which the Committee concurred, that every possible means should be taken to acquaint the public—and not merely the medical profession—with the seriousness and urgency of this matter. Dr. Barton thought the Chamber of Commerce of the United States would assist in supporting any sort of program that the Committee on Postwar Medical Service would set up to help the situation

On motion of Dr. Abell, seconded by Dr. Shoulders and carried, the subcommittee was empowered to act along the lines suggested in the discussion without the necessity of further reference to the whole committee.

Further Report of Subcommittee on Surplus Medical and Hospital Supplies—At the request of Father Schwitalla, chairman of the subcommittee, Dr. Fishbein presented the following statement concerning a conference held in Washington on May 8 at which he and Dr. Irons were present as representatives of the American Medical Association on the invitation of Surgeon General Parran:

Surgeon General Parran was requested by the Surplus Property Board to assume as a function of the Public Health Service the responsibility of making recommendations regarding the disposal of strictly medical surplus supplies The Surgeon General was reluctant to take over this duty and, since the Surplus Property Board must depend on a federal agency, it was decided to request Governor McNutt, as head of the Federal Security Agency, to appoint a special committee to include representatives of the medical profession, of the hospitals, of the dental profession, of public health and of sanitary engineering and similar professions in the health field. It is understood that Governor McNutt has agreed to appoint such an advisory committee to the Surplus Property Board

There will be a considerable amount of surplus medical equipment Under the law it apparently is desirable and feasible for the Surplus Property Board to designate areas in need from a medical and public health point of view and to designate the need in those areas It was said that the material even could be given outright to a needy area. In connection with the determination of what areas may be in need, it also would be necessary to determine whether hospitals, physicians and dentists are available in the areas to use equipment provided The facilities of the Bureau of Information should be of value in this connection.

There are certain priorities established under the law itself as to where the surplus materials may be offered—first to federal institutions, then to state and local institutions and then to nonprofit and voluntary institutions Educational institutions on a nonprofit basis also have a priority Then comes the question of priority for individuals, for veterans Regulations were published about three days ago as to the manner in which opportunity will be given to all to purchase this material.

It was stated at the Washington conference that the proposed advisory committee might list the minimum equipment necessary for a physician or dentist to establish himself in a needy area, and then the Surplus Property Board could assemble such equipment and furnish it to returning veterans at a discount

Dr Walter L. Bierring remarked that at the Conference of State and Territorial Health Officers in Washington on April 12 Mr. Rosenfield of the Surplus Property Board, Miss Switzer and others had urged that the state and local health agencies become more active in the matter of surplus property disposal and, as a result, the conference had adopted a resolution asking Surgeon General Parran to invite representatives of various interested organizations to create some sort of agency that could be of assistance.

Major Richard J. White, who is working on the problem of surplus medical and dental supplies as far as the Office of the Surgeon General of the Army is concerned, was introduced by Father Schwitalla. Major White stated: This is an absolutely long range program; the type of equipment at first available as surplus will be field equipment, which is not the type placed in station hospitals or in army hospitals in the United States but may be and can be adapted for general hospitals; there is a lot of medical material that was procured in 1917, which *was turned* over to the Office of Civilian Defense; we are in no position to state what we are going to have for surplus nor when we are going to have it but are looking toward surplus in the future, the long range; we are trying to get together with interested and informed groups in medicine to try to formulate some policy; the Surgeon General's Office is in accord with everything that has been done so far; there is an excellent opportunity for some group such as the Committee on Postwar Medical Service to formulate a plan for the returning physician and dentist who wants to secure some of the surplus material to set up his own office; it might be possible for this committee to formulate a policy whereby it could be recommended to the state medical societies that they establish a special section in their state committees and have some one at the headquarters of the disposal area concerned who can act as the go-between and keep the physicians and dentists who come back from service informed as to the availability of the surplus material so that he need not go to the retailer; there will be no competitive bidding in the long range program; it would be desirable if a central buying agent could be established in each state and form a group in each state of those who would like to have something done for the doctor and dentist who wishes to set up his own office in a location of his own choice—this would take care of the individual veterans who do not come under the priority categories

Dr. Fishbein thought the points mentioned by Major White might well be referred to the committee that is to be established by Mr. McNutt

Father Schwitalla reminded the Committee of the report on the surplus property matter which he had presented to the Committee at the March meeting and which had been tabled He requested authority to bring that report up to date, to withdraw the recommendations made therein and have it published The request was granted

Dr. Camalier said that the American Dental Association would be very glad to go along with the plans as expressed by Major White.

It was voted to request the representative of medicine on the proposed McNutt committee to bring the views set forth by Major White to the attention of that committee. Father Schwitalla stated that as chairman of the Subcommittee on Surplus Medical and Hospital Supplies he would interpret this action as a command for his subcommittee

Report of Subcommittee on Establishment of Medical Corps in Veterans Administration—Father Schwitalla, chairman of the subcommittee, told the Committee of a communication he had received from Mr. Watson Miller of the Federal Security Agency regarding the Rogers bill.

The Committee was informed by Dr. Fishbein that more letters had been received recently at the offices of the American Medical Association concerning the Veterans Administration and its difficulties than had been received on any subject at any previous time, that many were from physicians in service who are fearful that when they return from active duty they will be assigned to service with the Veterans Administration and that some hundreds already had been so assigned. He thought it was a function of the Committee on Postwar Medical Service to represent the medical profession in this matter and that some expression should go to the suitable government officials to the effect that these physicians enlisted in the respective branches of the armed forces and not in the Veterans Administration. He asserted that it is absolutely against everything that American medicine stands for to have these men forced into the Veterans Administration as a part of their service with the armed forces

Dr. Irvin Abell informed the Committee that at a meeting of a special advisory committee to the Veterans Administration in March a reorganization of the service was suggested, that a subcommittee was then appointed to formulate plans for such reorganization and that a report has been prepared and is ready for presentation.

The following statement was presented by Dr. E L Henderson, a member of the Executive Committee of the Board of Trustees of the American Medical Association, who announced that the statement had been adopted the previous day by the Executive Committee:

In November 1944 the Army Medical Department was directed to transfer at least 300 Medical Corps officers to the Veterans Administration, this number to include those officers in the zone of the interior who were formerly employed by the Veterans Administration as civilians Apparently about 100 men meeting the latter classification were so assigned and in addition some 200 others selected largely from among men who had been marked "limited service" Some of those thus assigned have protested and others are now protesting bitterly against these assignments on the ground that their enlistment was distinctly for military service and that assignment to the Veterans Administration cannot be thus characterized Physicians who have served with distinction in both the European and Pacific theaters of operation are now indicating by communications addressed to the offices of the American Medical Association the fear that they may be assigned on their return to the United States to service with the Veterans Administration The unwillingness to serve with the Veterans Administration is based not only on their belief that this cannot be considered military service but also on the point of view that competent, scientific medical care is difficult under the conditions that prevail in the veterans' hospitals

The Committee on Postwar Medical Service, which includes representatives of the American Medical Association, American College of Surgeons, American College of Physicians, American Hospital Association, Federation of State Medical Boards, Association of American Medical Colleges, Catholic Hospital Association, Advisory Board for Medical Specialties and other groups, after careful consideration of the problems involved, urges that the Secretary of War, the Secretary of the Navy and all others concerned with the activities of physicians voluntarily enlisted in the armed forces recognize the righteousness of the protests made by these medical officers against assignment to the Veterans Administration It is further urged that the needs of the Veterans Administration for physicians be met either by voluntary enrolment of men in the armed forces at the time of their release from the service or by recruitment of medical personnel from civilian sources

The statement presented by Dr. Henderson was unanimously adopted by the Committee on Postwar Medical Service. (Since the meeting of the Committee on May 12, the foregoing statement has been forwarded by telegraph to the Secretary of War and to the Secretary of the Navy and was printed in the editorial columns of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION for May 19, 1945)

It was brought out by Dr. Barton in the discussion on the Veterans Administration that there is an agreement in the offices of the Veterans Administration that attention will be paid to the expressed desire of a returning medical officer to go to a community of need before he may be assigned to duty with the Veterans Administration It was the opinion of the members of the Committee that the medical officers themselves know nothing about such an agreement.

Report of Subcommittee on Formulation of Lists of Medical Officers to Be Considered for Demobilization.—Dr. Frederick A. Coller, chairman of the subcommittee, presented the following report:

On April 21 there was a joint meeting in Washington of the directing board of the Procurement and Assignment Service and the Subcommittee on Formulation of Lists of Medical Officers to be Considered for Demobilization, which was represented by Dr Coller, chairman, Dr Bloedorn for Dr. Zapffe, Dr. Shoulders, Lieutenant Colonel Lueth and Father Schwitalla It was intimated that the Surgeon General of the Army would be willing to consider for discharge a small selected list of essential teachers This subcommittee was requested to obtain such a list through Dr Zapffe In brief, it was agreed that the list should be in three categories for each school first, those most urgently needed; second, those who are desirable but somewhat less urgently needed, and, third, important teachers but still less urgently needed In each category it was agreed that each school should limit the number of names submitted to 5 per cent of those of its teachers who were in service and that in any case no more than five names should be listed in each category.

The problem of the civilian need for physicians was discussed, and it was felt that the Procurement and Assignment Service was closely in touch with civilian needs through information received from its state chairmen It was felt that the relation between the state chairmen and the central office of the Procurement and Assignment Service might be tightened so that information concerning such needs could be presented to the Surgeon General of the Army through the Procurement and Assignment Service as soon as such needs occur

The need of industry for physicians did not seem to be pressing at the time We were informed that there had been very few requests sent to the Procurement and Assignment Service for aid in this field and that should such needs occur they will be handled by the Procurement and Assignment Service as heretofore

As far as the subcommittee is able to make out, there has been no important shortage of physicians in the public health field However, to clarify this situation it was determined that Dr. Victor Johnson would write a letter to the public health officers of the states to obtain factual evidence concerning the needs as they exist in this field

Dr. Zapffe reported that letters requesting the names of faculty members now in service whom the medical schools thought absolutely necessary to be returned were sent to the seventy-eight approved medical schools, that fifty-five replies had been received and that there are about 200 men on the lists who are urgently needed. Dr. Coller stated that the deans of some medical schools had had a communication from Surgeon General Kirk asking for lists of ten faculty members whom they would like to have returned and the order in which they wish them, and that confusion was created as the result of this duplication General Rankin stated that practically all of the medical schools had replied to the Surgeon General's letter, that it is not at all certain the plan can be worked out and that both the lists obtained through the direct communication of the Surgeon General and those submitted by the Committee on Postwar Medical Service will be used

There was considerable discussion on the methods to be used in the screening of the lists of needed faculty members, and it was decided that the lists obtained through the efforts of the subcommittee should be turned over to Colonel Lueth for use by the Surgeon General.

The report of the subcommittee was accepted and the committee continued

Question of Further Distribution of Information on Topics Considered by the Committee on Postwar Medical Service—The Chairman stated that in his opinion publication of the minutes of the Committee's meetings had been valuable He informed the members that a bibliograpy of all pertinent material which has appeared in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION has been prepared and that copies are available to any one interested. Copies of the bibliography were distributed among those present. He further stated that suggestions for further publicity would be welcomed

Refresher Courses for Medical Officers in Foreign Countries—Colonel Lueth reported that from personal letters it appeared that attempts were under way to give refresher courses for medical officers in Europe as a part of the educational program of the Army. It is believed such refresher courses will be continued in the near future. Definite information concerning this work will be given at a later time

Situation of the Medical Profession in the Philippines—The Chairman presented a letter that had been received from a medical officer now on duty in the Philippines in which concern was expressed as to what the profession in the United

States might do to aid the rehabilitation of medical education and the practice of medicine in the Philippines

It was the consensus of the Committee that all possible aid should be given but that no immediate plans can be made until the entire situation is clarified Measures are now being taken to obtain first hand information

Report of Subcommittee on Graduate Education of Physician Veterans—Father Schwitalla, chairman of the subcommittee, presented the following progress report which he stated had been approved via telephone by Mr H V Stirling of the Veterans Administration and was ready for release

PROGRESS REPORT OF SUBCOMMITTEE ON GRADUATE EDUCATION OF PHYSICIAN VETERANS

A meeting took place in the office of Mr H V Stirling, director, Vocational Rehabilitation and Education Service of the Veterans' Administration, on Saturday afternoon April 21 1945 The meeting was attended by Mr Stirling and three members of the Subcommittee on Graduate Education of Physician Veterans namely, Dr Victor Johnson, Lieut Col Harold C Lueth and Father Alphonse M Schwitalla, S J

The purpose of the meeting was to bring before Mr Stirling a number of questions which had been raised concerning the application of the educational provisions of the G I bill to the residencies in hospitals, particularly in nonuniversity hospitals

NUMBER OF VETERANS NOW IN EDUCATIONAL PROGRAMS UNDER PUBLIC LAWS 16 AND 346

As of the end of February 1945 there were in training under Public Law 16 a total of 11,937 (21 per cent) trainees 11 673 (21 per cent) cases were pending, 29,464 (52 per cent) had been denied training or were temporarily deferred from training and 3 128 (5 per cent) had terminated their training, the total in all groups being 56,202

Under Public Law 346 as of the same date there were in industrial training 17,583 veterans in institutional programs 17 029 and in "on the job training 554 Of those in institutional courses 589 were in 'below college' programs, 301 in junior colleges 406 in teachers colleges, 12 331 in colleges of arts and sciences and 3 402 in trade schools The number who discontinued their training is 2,679, of this number 181 had completed the work which they began, 854 interrupted it voluntarily, 1,052 discontinued the program voluntarily, 86 were declared unsatisfactory for their programs and 505 transferred from opportunities under Public Law 346 to opportunities under Public Law 16 No figures were specifically available for persons training in schools of medicine or dentistry at the present time

NUMBER OF VETERANS CHOOSING MEDICINE AND DENTISTRY

Mr Stirling was good enough to supply information concerning present trends in the number of applications for medicine and dentistry and allied fields among the persons who had come under his office, that is, under the Vocational and Rehabilitation Service One study had been made of a total of 9,359 applications approved by the regional offices under Public Law 16 In this group there were 38 applications requesting an opportunity to study dentistry, 81 to study pharmacy, 59 to study medicine and 18 to study chiropractic or osteopathy

In another study of the applications under Public Law 346, two groups of 5 000 applications as approved by the state agencies were each analyzed with the results given in the accompanying table

Analysis of Applications

Applications for	In the First Group of 5 000	In the Second Group of 5 000
Predentistry	14	18
Dentistry	530	503
Medicine	184	203
Premedicine	69	82
Pharmacy	34	37
Chiropractic	17	18
Osteopathy	2	3
Chiropody	4	7

GENERAL STATISTICS ON VETERANS EDUCATION

A fairly complete statement concerning the general statistics on veterans' education is contained in Bulletin No 80, Higher Education and National Defense of the American Council on Education March 27, 1945, page 6

'During January 1945 the number of veterans entering on training Public Law 16 was 3 872 as compared with only 2 138 new trainees under Public Law 346 In February the numbers were 1 261 and 2 027 respectively It is significant that the number enrolling during February, when the second semester begins in many colleges was only 2,391 under the two acts While the relative numbers were reversed for the two months the larger number for January and February combined came under Public Law 16 If this trend continues there will be more veterans in colleges and universities under the vocational rehabilitation program than under the G I bill until the beginning of demobilization of large numbers of nondisabled veterans"

Statistics such as these are obviously of great value to medical educators and hospital executives for their planning

TUITION CHARGE MADE BY HOSPITALS

Mr Stirling was asked whether any change had been made in the provisions previously announced in the Committee's memorandum of Oct 16, 1944 It was there stated as follows "The law provides that if the institution has no established tuition fee, or if the administrator deems the established tuition fee to be inadequate compensation, the administrator is authorized to provide for the payment, again, however, with the $500 ordinary school year limitation" Mr Stirling said that there has been no change with reference to this provision and that, therefore a hospital may charge tuition for a residency

Mr Stirling's attention was called to Mr McCarran's bill S 181, introduced on March 22, 1945 and now in the hands of the Committee on Finance of the Senate, the essential provision of which reads as follows "And provided further, that if a publicly supported institution or private institution exempt from tax under section 101 (6) of the Internal Revenue Code has no established tuition fee or if the established tuition fee of any such institution is less than the actual cost to such institution of furnishing the education or training the administrator is authorized to provide for the payment to such institution with respect to any such person, of the actual cost of furnishing such education or training but not to exceed $500 for an ordinary school year' Mr Stirling commented that this was essentially the understanding which he had of the intent of the Servicemen's Readjustment Act of 1944

PAYMENT OF SALARIES TO RESIDENTS UNDER THE G I BILL

Mr Stirling was then asked whether the previous understanding of the Committee that veterans who are appointed residents in hospitals but who participate in the benefits of the G I bill may continue to receive a salary from the hospital Mr Stirling replied that there is no question in his mind but that nothing in Public Law 346 prevents either the payment of a salary by the hospital or the acceptance of a salary by the resident, provided the limitations which are recognized under Public Law 16 are applicable also under Public Law 346 He felt, however, that there should be no difficulty whatever in meeting the provisions to which he refers The particular provision of Public Law 16 reads as follows "That when the course of vocational rehabilitation furnished to any person as herein provided consists of training on the job by an employer, such employer shall be required to submit monthly to the administrator a statement under oath showing any wage, compensation or other income paid by him to such person during the month, directly or indirectly and based on such sworn statements the administrator is authorized to reduce the pension of such person to an amount considered equitable and just, but not below the amount of pension or retirement pay to which he would be entitled for service connected disability if not following a course of vocational rehabilitation" In a memorandum of the Veterans Administration of Public Law 16 dated Dec 15, 1943 managers are authorized to reduce the pension of a person when the employer trainer pays wage or compensation in whole or in part if the sum thus paid "when added to the increased pension exceeds the minimum entrance wage paid by the employer trainer to an employee in the particular job for which the person is being trained" A provision which bears on this point is found in the Veterans Administration Instruction No 2 dated Jan 18, 1945, page 8, paragraph 19 (b), which reads as follows

"Where the veteran is receiving compensation for productive labor, performed as part of his apprenticeship or other training on the job, the amount of subsistence when added to his current monthly salary or wage based on the standard work week exclusive of overtime, shall not be in excess of the standard beginning salary or wage payable to a journeyman workman in the occupation or trade in which training is being given, similarly based on the standard work week exclusive of overtime"

THE ADMINISTRATOR'S SPECIAL COMMITTEE ON VOCATIONAL REHABILITATION, EDUCATION AND TRAINING PROBLEMS

Mr Stirling kindly supplied the names of those who are serving as members of the Administrator's Special Committee on Vocational Rehabilitation, Education and Training Problems The committee members are as follows

Dr Arthur Andrews, president Grand Rapids Junior College, Grand Rapids Mich

Dr Horace S Ford, treasurer, Massachusetts Institute of Technology, Cambridge, Mass

Dr R W Kent, director, Essex County Vocational Schools Newark, N J

Dr Thurman D Kitchin, president, Wake Forest College, Wake Forest, N C

Dr Robert G Sproul, president, University of California, Berkeley, Calif

Dr Robert B Stewart, comptroller Purdue University, Lafayette Ind chairman of the committee

Dr Rufus C Harris, president, Tulane University, New Orleans

Perhaps attention might be called to the desirability of adding to this special committee the names of an educator or of educators who are familiar with the medical aspects of the many educational problems with which the Veterans Administration is now dealing

STUDENTS OF NONAPPROVED SCHOOLS

The question was asked whether nonapproved schools of medicine were receiving student veterans under the G I bill The members of the subcommittee are completely satisfied that from such information as is now available, no serious difficulty need at present be foreseen

APPROVAL AGENCIES FOR INSTITUTIONS IN THE STATES

Mr. Sterling was asked whether he could furnish to the Committee a list of the organizations functioning in the various states as the approval agencies for institutions approved as qualified and equipped to furnish training to veterans under Public Law 346. He was kind enough to accede to this request and furnished the accompanying list, indicating, however, that in many instances "there has been no specific designation by the governor of the approval agency in a given state" Mr. Stirling's list has been compiled from the best information available and represents the conditions up to April 30, 1945.

The report was accepted and the subcommittee continued.

Informational Reports.—Wartime Graduate Medical Meetings: Dr. F. F. Borzell reported for the Central Committee of the Wartime Graduate Medical Meetings that the work of that committee continues to be received enthusiastically but that some difficulty is now being encountered in finding speakers for the Army, Navy and Air Corps refresher courses.

Approval Agencies

State	Agency
Alabama	Department of Education
Arizona	Department of Public Instruction
Arkansas	Department of Education
California	Department of Education; Division of Readjustment Education

Virgin Islands	(No agency designated)

Federation of State Medical Boards: Dr. Walter L Bierring stated that the Federation had received a number of inquiries from graduates of unapproved schools who have served as medical officers in the armed forces as to whether their military service would be given special consideration when they applied for licensure in those states where graduates of unapproved schools are not eligible at the present time.

Time and Place of Next Meeting.—It was decided that the next meeting of the Committee should be held at American Medical Association Headquarters in Chicago on Saturday, June 23, 1945.

The meeting adjourned at 1:13 p. m.

H. H. SHOULDERS, M.D., Secretary.

ECONOMIC ASPECTS OF FUTURE MEDICAL PRACTICE

Lieutenant Colonel Harold C. Lueth
Surgeon General's Liaison Officer
MEDICAL CORPS, ARMY OF THE UNITED STATES

The Committee on Postwar Medical Service mailed a questionnaire to all medical officers on duty requesting information as to their desires in regard to future practice. Previous studies of the answers contained in the 21,029 questionnaires returned have appeared in THE JOURNAL.[1] One set of questions referred to economic aspects of medical practice, and the results are discussed in this paper.

TYPE OF MEDICAL PRACTICE DESIRED

There were 4,326 medical officers who indicated a desire to engage in general medical practice after release from service This constituted only about three fourths of those who entered the armed forces from general practice. Nearly two thirds of all medical officers, 12,627, indicated that they were interested in special medical practice in the future They were about equally divided between those who expressed a desire to engage solely in specialty practice, 6,456, and those who expressed a desire to engage in specialty practice combined with part time teaching, 6,171.

Medical officers who were interested solely in future specialty practice seemed to favor communities of 25,000 to 250,000 population. There were only 27 who wanted to go to communities of less than 2,500, 906 who wanted to go to communities of 2,500 to 25,000, 2,539 who wanted to go to communities of 25,000 to 250,000 and 949 who wanted to go to communities of more than 250,000 population. Nearly one third of the group of medical officers gave no indication of the preferred size of community.

There were 2,821 medical officers who expressed a desire to engage in medical practice on a full time basis. Included in this group were 278 men who desire to become full time teachers.

ACCEPTABLE MONTHLY SALARIES

One of the questions asked was "What is the *minimum* monthly salary you would accept on a salary basis?" A wide range of answers was given. The median monthly salary mentioned was $583. There were 1,485 medical officers who would accept a monthly salary of $400 to $499, 2,610 medical officers who would accept a monthly salary of $500 to $599 and 1,090 medical officers who would accept a monthly salary of $600 to $699. There was fairly even distribution among the various graduation groups.

VOLUNTARY REDISTRIBUTION OF MEDICAL OFFICERS

Eleven per cent, or 2,364 medical officers, expressed willingness to go to a different community than that from which they came if a subsidy was provided for several months. About 13 per cent of medical officers (2,817) stated that they would be willing to go to an area needing physicians if there was an office established. More than 15 per cent (3,284 medical officers) were willing to move to an area in need of physicians if diagnostic facilities were available. Nearly 29 per cent (6,091) would go to a community in need of a doctor if there were hospital facilities. The proportions in each graduation group who would go to a community needing physicians with office established, subsidy provided, diagnostic facilities or hospital facilities were about equal

A few men wanted to go to communities of less than 2,500 population. There were 41 who would go if a subsidy was provided, 43 if there were diagnostic facilities, 56 if an office was established and 74 if there were hospital facilities available. About one fifth of all men who were willing to relocate wished to go to cities of 2,500 to 25,000 population. Six hundred and forty-three medical officers would go to such cities if there was an office established, 531 medical officers if there was a subsidy

1. Lueth, H. C.: Postgraduate Wishes of Medical Officers: First Report on 21,029 Questionnaires, *J. A. M. A.* **127**: 759 770 (March 31) 1945; The Medical Officer Returns to Civilian Practice, ibid **127**: 1039 1043 (April 21) 1945, The Medical Officer and Future Industrial Practice, ibid. **128**: 93 95 (May 12) 1945; Results of Pilot Questionnaire to Physicians in Service, ibid **125**: 558 560 (June 24) 1944

provided, 710 if there were diagnostic facilities and 1,327 if there were hospital facilities

Many men gave no indication of the size community they would go to but said they would go if an office was provided (631), a subsidy was provided (481), diagnostic facilities were provided (641) and hospital facilities were provided (1,166)

FULL TIME MEDICAL PRACTICE

About 85 per cent of medical officers indicated that they did not desire to remain in government service Medical officers of the regular medical corps or governmental agencies were considered separately and constituted a group of 532 officers There were 237 Regular Army officers, 181 Regular Navy officers, 15 United States Public Health Service officers, 10 Regular Veterans Administration officers and 4 regular officers from other governmental agencies who indicated their desire to remain in government service, or a total of 2,501 In addition, 49 regular officers stated that they did not want to remain in government service

Of Reserve officers 672 men were willing to accept army service Naval medical service attracted 406 officers About the same number of men (411) chose the United States Public Health Service There were 435 medical officers who desired service with the Veterans Administration About one third of these officers graduated from medical school before 1930

GROUP AND PRIVATE PRACTICE

The questionnaires of medical officers were divided into several categories—those wanting to reengage in individual private practice (8,041), those not desiring to reengage in private practice (1,345), those desiring private practice with a group (10,994) and those who gave no indication of their wishes (649) The distribution by graduation groups is shown in the accompanying table

Answers to Group Practice Question

Graduation Group No	Dates of Graduation	Want to Reengage in Private Practice *	Do Not Desire to Reengage in Private Practice	Desire Private Practice with a Group	No Indication of Wishes	Total
1	1941 1945	1,432	181	2,608	142	4,363
2	1938 1940	1,422	198	2,461	124	4,205
3	1933 1937	1,472	180	2,053	98	3,802
4	1930 1934	1,999	302	2,304	119	4,724
5	1920 1929	1,592	287	1,336	115	3,330
6	Before 1920	194	197	143	91	625
Total		8,041	1,345	10,994	649	21,029

* No indication as regards group practice It also includes men who want to enter private practice

CONCLUSIONS

1 More than one fourth, or 5,785 (27 4 per cent) medical officers, were formerly in general medical practice The smallest number of men (624) came from communities of less than 2 500 population and more than three times that number came from cities of 2,500 to 25,000, cities of 25,000 to 250,000 and cities of over 250,000

2 About one third (7,282 medical officers) had been in special practice in civilian life More than three fourths of the specialists came from large cities, and many had been certified by American boards

3 There were 4,326 medical officers who indicated a desire to engage in general medical practice, or only about three fourths of those who came from general practice to duty with the armed forces In contrast, more than half again as many men who were originally in specialty types of practice before coming to duty (7,282) indicated that they would like to engage in specialty practice after the war (12,627) Medical officers interested in future specialty practice seemed to favor communities of 25,000 to 250,000 population

4 A wide range of answers was given to the question as to the minimum acceptable monthly salary that medical officers would accept in the future The median monthly salary was $583, and there were slight variations for the different sized communities and larger variations between the different graduation groups

5 Eleven per cent (2 364 medical officers) were willing to go to a new community in need of physicians if a subsidy was provided for several months About 13 per cent of medical officers or 2 817, stated that they would be willing to go to an area needing physicians if there was an office established More than 15 per cent, or 3,284 medical officers, would go to such areas if there were diagnostic facilities, and nearly 29 per cent, or 6,091, if there were hospital facilities In general a larger number of young men indicated their willingness to locate in new areas than older medical officers

6 About 85 per cent of medical officers indicated that they did not desire to remain in government service

7 Private practice, either individually or as part of a group, was the choice of more than four fifths of medical officers There were 8,041 medical officers who expressed a desire to engage in the individual private practice of medicine and 10,994 who desired to engage in private practice as a member of a group

Medical Legislation

MEDICAL BILLS IN CONGRESS

EMIC Program

H J Res 212 has passed the House and Senate, appropriating an additional $2,200,000 to provide medical, nursing and hospital maternity and infant care for the wives and infants of enlisted men during the remainder of the present fiscal year, which will end June 30 There is pending in the Senate Committee on Appropriations the regular appropriation bill for the Labor Department, which will make available for this program $44,189,500 for the fiscal year beginning July 1

Dental Health

Three identical bills have been introduced to provide assistance to states in developing and maintaining dental health programs, S 1099, introduced by Senator Aiken, Vermont, for himself and Senator Pepper, Florida, H R 3414, introduced by Representative Traynor, Delaware, and H R 3412, introduced by Representative Brehm, Ohio This legislation would create a National Dental Health Council and would authorize for each fiscal year a sum sufficient to enable the Surgeon General of the United States Public Health Service (1) to assist, through grants and as otherwise provided, states and political subdivisions in establishing and maintaining adequate measures for the prevention, treatment and control of dental diseases and the development and maintenance of effective means for the education of the public concerning such diseases, (2) to make available to states and political subdivisions and to educational institutions and other nonprofit agencies grants for approved studies, investigations and demonstrations in dental health care and education projects, and (3) to conduct studies and demonstrations and to collect information relative to the prevention, treatment and control of dental diseases

Official Notes

DOCTORS LOOK AHEAD

Remaining programs in the series of network broadcasts by the NBC and the American Medical Association will be on the air June 23 and 30 except in Chicago

Doctors Look Ahead is broadcast each Saturday at 4 30 p m Eastern War Time (3 30 p m Central War Time, 2 30 p m Mountain War Time, 1 30 p m Pacific War Time) except in Chicago where each week's program as broadcast on the network will be heard on the next Saturday afternoon at 3 p m Central War Time

The programs remaining are as follows

June 23 Postwar Doctor Problems in medical education and their influence on the public health Guest speaker Dr Victor Johnson, Secretary American Medical Association Council on Medical Education and Hospitals

June 30 Health in Schools A program devoted to health education and related topics in our schools, where doctors look ahead to greater progress in the next decade Speaker Dr Charles C Wilson, Teachers College, Columbia University, speaking from New York

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

Dr. Ross Reappointed Health Officer.—Dr. Thomas T. Ross, state health officer, Little Rock, was reappointed for a four year term when the state board of health met in quarterly session April 19. His new term begins July 1, it is reported.

District Meeting.—The Fifth Councilor District Medical Society was addressed in Magnolia, May 22, by Drs. William Decker Smith, Texarkana, and Stanley George Wolfe, Shreveport, La., on "The Gastroscope—Its Use in the Examination of the Stomach" and "Plasma Fractionation—Its Use in the Diagnosis and Treatment of Disease" respectively.

COLORADO

Dr. Parran Addresses Open Meeting.—Dr. Thomas Parran, Surgeon General of the U. S. Public Health Service, addressed an open meeting of physicians and interested lay persons under the auspices of the Colorado State Medical Society at the Shirley-Savoy Hotel, Denver, May 24. His subject was "Pending Legislation Relative to Public Health and Hospitals for the Future." The talk was a feature of a two day meeting of the Colorado Public Health Association which was being conducted by a team of speakers sponsored by the American Public Health Association. These speakers included Drs. Karl F. Meyer, San Francisco, and George M. Wheatley, New York, on "Legislative Proposals for Medical Care in California" and "Rheumatic Fever and Its Public Health Significance" respectively.

DISTRICT OF COLUMBIA

Personal.—Dr. Daniel L. R. Borden has resigned as chairman of the district board of police and fire surgeons, effective April 16. Dr. Borden has been on leave from the board since 1941, when he entered military service.

The Curtis Lecture.—Dr. Ulysses Grant Dailey, Chicago, delivered the fifth annual Austin M. Curtis Memorial Lecture before the faculty and students of Howard University College of Medicine, Washington, May 28, on "Treatment of Thyrotoxicosis."

Clinical Society Inaugurates Distinguished Service Award.—The Georgetown Clinical Society on April 19 presented its first G award for distinguished service in the practice of medicine or surgery to Comdr. Joseph J. Mundell (MC) at a dinner meeting in the Statler Hotel. This was the first presentation of the new annual award to be given in the form of a G plaque and an inscribed certificate to be made to an alumnus of the Georgetown University School of Medicine who distinguished himself in private practice and in service to the school of medicine. Commander Mundell graduated at Georgetown in 1903 and has been practicing in the district for thirty-nine years. For the past eleven years he has been professor and head of the department of obstetrics at Georgetown. He helped found the Georgetown Clinical Society in 1906.

FLORIDA

Annual Graduate Short Course.—The thirteenth annual graduate short course for physicians will be held June 25-30 at the George Washington Hotel, Jacksonville. The first three days will be devoted to medicine and the last three to surgery. Preliminary plans call for the following faculty:

Dr. Eugene A. Stead Jr., professor of medicine, Emory University School of Medicine, Atlanta, Medicine.
Dr. Robert L. Sanders, associate professor of surgery, University of Tennessee College of Medicine, Memphis, Surgery.
Dr. Herbert C. Miller Jr., Yale University School of Medicine, New Haven, Pediatrics.
Dr. Oren Moore, dean of obstetrics, Southern Pediatric Seminar, Charlotte, N. C., Obstetrics.
Dr. Edwin C. Hamblen, chief of division of endocrinology, Duke University School of Medicine, Durham, N. C., Gynecology.
Surgeon Richard C. Arnold, U. S. Public Health Service, venereal disease research laboratory, Staten Island, N. Y., Venereal Diseases.

Additional information may be obtained from Dr. Turner Z. Cason, Jacksonville, director of the department of medicine, Graduate School, University of Florida.

Oldest Medical Society in State.—On May 25 the Duval County Medical Society observed its ninety-second anniversary. The society was created in 1853, eight years after Florida became a state, and was the first component society of the state medical association to be established. Its first officers were the late Drs. John S. Murdoch, president; W. J. L'Engle, secretary, and Richard P. Daniel, treasurer. The state medical journal reports that apparently there were no other county medical societies in Florida until after the war between the states. In a history prepared by Dr. J. Webster Merritt, Jacksonville, it is shown that the late Dr. James Hall represented the profession in and around Jacksonville for a quarter of a century before the Floridas, east and west, were ceded to the United States by Spain. His successor, the late Dr. A. S. Baldwin, arrived in Jacksonville in 1838, and the Duval County Medical Society was created at his instigation in 1853. The medical history written by Dr. Merritt is now being published serially in the *Journal of the Florida Medical Association*.

GEORGIA

New Law Asks Parents to Register Births.—On July 1 a law will become effective making the registration of births the responsibility of the parents. The medical attendant will be responsible for supplying the medical record. *Georgia's Health* believes that parent participation will result in better and more accurate reporting. Two particular advantages will be obtained from the filing of a separate medical report, it was stated. Medical information useless to the lay person will be removed from the legal certificate. Second, because it is a confidential report, the physician may report medical items of public health interest without prejudicing the interests of his patient.

Report of Warm Springs Foundation.—During the fiscal year 1944, 543 patients received 36,549 hospital days' care at the Georgia Warm Springs Foundation, according to its annual report. Of the total, 289 received financial assistance, this group receiving 22,852 hospital days' care, or 62.52 per cent of the total hospital days' care. The average daily number of patients in residence throughout the year was 100. Newspapers reported recently that a syndicate of life insurance companies is making payments to the foundation on a $560,000 policy taken out by the foundation in 1930 on the life of Franklin D. Roosevelt, then governor of New York. The foundation paid the premium and also was the beneficiary, it was stated.

ILLINOIS

House Committee Urges Passage of Pure Food Bill.—A bill providing for state control of food, drug and cosmetic standards and advertising in intrastate commerce was recommended for passage May 28 by the house committee on public health. Similar measures were sponsored in 1941 and 1943, but this is said to be the first time that the bill was reported to the floor of the house.

Payment of Physicians' Bills for Employees.—S. DeWitt Clough, president and general manager, announces a plan for payment of physicians' bills for employees of Abbott Laboratories, North Chicago, according to *Industrial Medicine*. Employees will be reimbursed for physicians' bills incurred in the hospital, at home or at the doctor's office. The entire cost of the program, which will benefit approximately 2,800 employees of the laboratories and its seventeen branches in the United States and Canada, will be paid by the company. Under a medical expense plan, which is underwritten by Equitable Life Assurance Society of the United States, an employee will be repaid up to $2 for each visit to a doctor's office or at a hospital and up to $3 for each visit by a physician to the employee's home. Payment will be limited to one visit each day and to a maximum of fifty visits in any one calendar year.

Chicago

Ninety-Four Years of Age.—On May 23 Dr. Samuel Collins Buchan observed his ninety-fourth birthday. Dr. Buchan graduated at Bellevue Hospital Medical College, New York, in 1877 and came to Chicago in 1919.

Gilbert Wynekoop Released from Mental Hospital.—According to newspaper reports, Dr. Gilbert H. Wynekoop was held sane and released from the Illinois Security Hospital at Menard on a writ of habeas corpus issued by Judge L. P. Harris in the circuit court of Randolph County May 17. In 1934 the Illinois state department of registration revoked his license because he had been adjudged insane.

Nathanson Denied Court Review.—The U. S. Supreme Court on June 4 denied a motion for review of the case of Dr. Frank L. Nathanson, who in May 1942 was convicted of conspiracy to commit abortion. At the time he was sentenced by John A. Sbarbaro, then a judge of the criminal court, to a year in the county jail and to pay a fine of $2,000. He was released on a $5,000 bond pending his appeal. His conviction followed the testimony of a woman who claimed that Nathanson had performed an abortion on her. He is said to have been arrested on similar charges eight times previously. Newspapers reported that the appellate court upheld the conviction on Dec. 17, 1943 and the state supreme court upheld it on January 18 of this year.

Special Society Elections.—At the annual meeting of the Chicago Gynecological Society, May 18, the following officers were chosen: Drs. James E. Fitzgerald, president; Ralph A. Reis, president-elect; Eugene A. Edwards, vice president; Herbert E. Schmitz, secretary, and Henry Buxbaum, treasurer.——New officers of the Chicago Society of Internal Medicine elected May 21 include Drs. Samuel Soskin, president; Laurence E. Hines, vice president, and Howard L. Alt, secretary-treasurer.——Dr. Frederick W. Schacht was elected president of the Chicago Urological Society at its annual meeting on May 24, Dr. Harry J. Dooley vice president and Dr. James W. Merricks secretary-treasurer.——The Chicago Orthopaedic Society recently chose Dr. Charles N. Pease president-elect. Other officers include Drs. Walter R. Fischer, president; Arthur H. Conley, vice president; John R. Norcross, secretary and Manley A. Page, assistant secretary.

INDIANA

Executive Secretary for Indianapolis Medical Society.—Ray E. Smith, Indianapolis, a member of the state board of tax commissioners, has been appointed executive secretary of the Indianapolis Medical Society, a newly created position. Mr. Smith, whose resignation from the tax board was effective June 1, will serve as assistant to Mr. Thomas A. Hendricks, executive secretary of the Indiana State Medical Association, dividing his time between the two offices.

KENTUCKY

Hospital Construction Program.—On May 17 Governor Simeon S. Willis signed an $84,000 contract with three architects to draft plans for construction of five tuberculosis hospitals, one each in Madisonville, first district; Paris, third; Ashland, fourth; London, fifth, and Glasgow, sixth. Existing facilities in Louisville in the second district were embraced in forming the areas, explains the Hopkinsville *New Era* in discussing the districts set up by the 1944 general assembly in creating the tuberculosis sanatorium commission. The legislature set aside $1,500,000 to start construction and empowered the commission to determine which sanatorium would be constructed first. It is expected that each hospital will have about 100 beds.

MARYLAND

New Bacteriologist at Maryland.—Oscar N. Allen, Ph.D., professor of bacteriology and plant pathology at the University of Hawaii, Honolulu, since 1940, has been appointed head of the department of bacteriology at the University of Maryland, College Park. Dr. Allen succeeds Lawrence H. James, Ph.D., who has opened a consulting laboratory in Chicago.

De Lamar Lecture in Hygiene.—Dr. George Baehr, clinical professor of medicine, Columbia University College of Physicians and Surgeons, New York, gave the De Lamar Lecture in Hygiene at the Johns Hopkins University School of Hygiene and Public Health, May 17. His subject was "Medical Service Under the Health Insurance Plan of Greater New York."

MASSACHUSETTS

Physician Honored.—Dr. Alice S. Woodman, associate professor of histology and embryology and for thirty-eight years a member of the faculty of the Boston University School of Medicine, was honored at a special gathering by students and members of the faculty recently to mark her retirement at the end of June. Dr. Woodman graduated at Boston in 1903.

Diabetes Mellitus in Relation to General Medicine.—A graduate course will be conducted at the New England Deaconess Hospital, Boston, July 9-11 and October 1-3, on "diabetes mellitus in relation to general medicine." It will consist of ward teaching and didactic presentation of such topics as pathology of diabetes, alloxan and experimental diabetes, treatment with diet and the various insulins, hypoglycemia, diabetes in childhood and pregnancy, cardiovascular disease, management of complications including gangrene, pulmonary diseases, ocular and dermatologic lesions, diabetic neuropathy and ketosis and the treatment of diabetic coma. Instructors of the course will include Drs. Elliott P. Joslin, Howard F. Root, Priscilla White, Charles Cabell Bailey, Shields Warren, Leland S. McKittrick, John Herbert Waite, William P. Beetham, Richard H. Overholt, Arthur M. Greenwood, Orville T. Bailey and George W. Thorn, Harry C. Trimble, Ph.D., and Thorne M. Carpenter, Ph.D. Applications for the course should be made to the assistant dean, course for graduates, Harvard Medical School, Boston 15.

MICHIGAN

New Academy of Medicine.—The Southwestern Michigan Academy of Medicine was formally organized in St. Joseph, May 11, to bring to members of the profession in Berrien County prominent speakers. According to the St. Joseph *Herald Press* the new group is not to supplant the existing Berrien County Medical Society in any way. Officers of the new academy of medicine include Drs. Donald W. Thorup, Benton Harbor, president, and Robert C. Conybeare, Benton Harbor, secretary.

Campaign on Rheumatic Fever.—The Michigan State Medical Society and the Michigan Crippled Children's Commission are planning to launch a statewide campaign against rheumatic fever July 1. The two groups have been sponsoring a program in seven counties of the upper peninsula for the past two years. Patients were treated with the sulfonamides, and the experiment has proved sufficiently successful to carry on the statewide program with special emphasis in the congested areas. Every facility of the Michigan Crippled Children's Commission and of the state society is to be made available to the family physician, who will be invited to make full use of the commission's resources for blood and heart tests and for taking roentgenograms. The commission will pay the cost of care for children whose families are financially unable to meet the usual charges, which frequently are high because of the long hospitalization and convalescent period. In the cases in which private physicians cannot devote much time because of the long convalescent stage he may refer his patients to the pediatricians associated with the commission. Present plans call for a closer supervision of the sick child, special consultation service of pediatricians and cardiologists and follow-up care in the family.

NEW JERSEY

Division of Migrant Labor.—*Industrial Hygiene News Letter* reports the establishment of a division of migrant labor in the New Jersey Department of Labor to cooperate with the state department of health in prescribing minimum standards for sanitation and preventive and curative health centers for migrant workers. Through the state department of health, the commissioner of labor will provide essential medical, clinical, and hospital facilities; through the state director of health, he will exercise powers of a local health officer with respect to communicable diseases in migrant camps.

State Medical Election.—Dr. Frank G. Scammell, Trenton, was chosen president-elect and Dr. Samuel Alexander, Park Ridge, was installed as president of the Medical Society of New Jersey at the meeting of its board of trustees in Atlantic City, May 23. Other officers include Drs. Royal A. Schaaf, Newark, and J. Howard Hornberger, Roebling, vice presidents; Alfred Stahl, Newark, secretary, and George J. Young, Morristown, treasurer. The board, which met in place of the 179th annual convention of the society, scheduled five public meetings throughout the state in defense of what is called "the American way of medicine," according to the New York *Times*. The sessions were to be held in Atlantic City June 11, Camden June 12, Trenton June 13, Paterson June 14 and Newark June 15 and will represent the five judicial districts of the state society.

NEW YORK

Typhoid Carriers.—A total of 480 typhoid carriers were under supervision in upstate New York at the close of 1944, according to *Health News*. Forty-one new carriers were added to and 35 were removed from the register during the year. Twenty-three were discovered as a result of epidemiologic investigation of sporadic cases of typhoid, 4 by means of release cultures, 10 accidentally as a result of routine culturing, and 1 on the basis of information furnished by the

New York City Department of Health Three previously discovered carriers were added to the register, these carriers had been residing temporarily out of the state Of the 35 carriers whose names were removed from the register, 23 died, 6 were released from restrictions after the submission of the required number of negative fecal and duodenal specimens following cholecystectomy, while the names of 6 others were removed because of change of residence of the carrier to a community outside the jurisdiction of the department Noteworthy is the fact that only 97 cases of typhoid were reported to have occurred in the upstate area during 1944 Since the best evidence indicates that an average of 3 per cent of typhoid patients become chronic carriers, it is assumed that not more than 3 chronic carriers will develop from these cases On the other hand, during the same period 23 carriers died These data indicate the extent to which the typhoid problem is diminishing in New York State

New York City

Heart Association Moves.—The New York Heart Association, Inc, is now located in the New York Academy of Medicine, 2 East 103d Street

New Drug Exhibit.—On October 1 a drug exhibit will be opened at the New York Academy of Medicine which will be unrestricted as to subject and will include a variety of significant and new therapeutic agents The first drug exhibit of the academy opened Oct 9, 1944 and will be dismantled some time this month This exhibit was restricted to items bearing on the treatment of infections Thirty-eight pharmaceutical organizations participated in the current exhibit

United Medical Service Extends Service.—At an increased rate of 12 cents a month the United Medical Service, Inc, on May 23 offered its subscribers an additional service covering payment of medical bills in hospitals Newspapers reported that the new plan, which would provide payment for such hospitalized cases not requiring surgery or obstetric cost such as pneumonia, heart trouble and kidney disease, further broadens the services offered by organized medical societies in the service

Physician Sentenced for Bandage Diversion—Dr Abraham Freitag, Brooklyn, who pleaded guilty May 25 to violation of War Production Board priority regulation through the diverted sale of three million yards of bandage material intended for the armed forces into production of civilian goods, was sentenced May 31 to three years in prison and fined $100,000, newspapers reported (THE JOURNAL, April 14, p 1002) Francis G Caffey, federal judge, imposed the sentence which is said to be the "heaviest black market sentence ever imposed" in the New York area Dr Freitag, whose action was characterized by U S Attorney John F X McGohey as 'one of the meanest frauds ever perpetrated in this district," was given until June 18 to surrender

NORTH CAROLINA

New Hospital Control Board and Advisory Commission—Governor Cherry has appointed fifteen members of the new North Carolina Hospitals Board of Control authorized by the last general assembly The board is composed of one member from each of the state's twelve congressional districts and three members at large Among physician members of the board are Drs Yates S Palmer, Valdese, representing the tenth district and Thomas V Goode, Statesville, ninth district The governor also appointed a twelve man advisory commission to assist the hospital board of control and named Dr Hubert B Haywood, Raleigh, chairman Other members of the commission include

Dr Coy C Carpenter, Winston Salem dean of the Bowman Gray School of Medicine of Wake Forest College
Dr Wilburt O Davison, Durham, dean of the Duke University School of Medicine
Dr Walter R Berryhill Chapel Hill dean of the University of North Carolina School of Medicine
Dr Maurice H Greenhill Durham, in the psychiatric department of Duke Hospital
Dr George T Harrell Jr Winston Salem, professor of internal medicine of the Bowman Gray Medical School
Dr Lois B T Stanford Durham on the staff of Watts Hospital, only woman member of the committee and former member of the state hospital board of control
Charles C Poindexter, Greensboro past president of the North Carolina Dental Society and former member of the hospitals board of control
Dr James W Vernon, Morgantown, superintendent, Broadoaks Sanatorium
Dr Charles T Stroupe, Goldsboro, in the field of internal medicine, with considerable experience in the work of the Negro hospital at Goldsboro
Dr Paul F Whitaker, Kinston, president of the North Carolina Medical Association
Dr Carl V Reynolds, Raleigh secretary of the state board of health

OHIO

Birthdays of Physicians—Dr John H Norris, Fostoria observed his ninetieth birthday May 13 Dr Norris first located in Bowling Green in 1877, moving to Fostoria in 1889, where he has been practicing since that time——Dr Auguste Rhu, Marion, celebrated his ninety-sixth birthday April 5 According to the state medical journal, Dr Rhu is believed to be the oldest practicing physician in the state

Edward Malone Retires—Dr Edward Fall Malone, professor of anatomy at the University of Cincinnati College of Medicine, Cincinnati, will retire, effective July 1 Dr Malone is retiring at his own request because of ill health He joined the staff of the University of Cincinnati in 1910 as assistant professor of anatomy, in 1918 he was made professor of histology and in 1925 Francis Brunning professor of anatomy and director of the department His successor has not been announced

Tuberculosis Control Program.—For the first time in the history of the state, a widespread tuberculosis control program has been inaugurated by the state department of health involving patients and employees in all state welfare department institutions Nearly 40,000 patients and employees will soon undergo chest x-ray examinations as part of the control program, according to the state medical journal A mobile unit, including a physician and a technician, will be lent by the United States Public Health Service for the survey

Ohio Medical Indemnity—The Ohio State Medical Association on May 23 filed papers of incorporation for the Ohio Medical Indemnity Inc The insurance company, which will be controlled by the state medical association and operated on a statewide basis will provide indemnity for obstetric and surgical expenses and will be available to participants to Blue Cross hospital plans in the state According to the Cleveland *Plain Dealer* the company will start business with $100,000 capital assets and a cash surplus of at least $30,000 funds to be raised through the sale of stock to Ohio physicians and others interested in the plan The benefits at the start will range from $10 to $150, depending on the disability and payable to the policyholder The *Plain Dealer* stated that the Ohio State Medical Association invited the Cleveland Hospital Service Association to cooperate with the physicians in their insurance plan but this organization decided to go ahead with plans for its own indemnity insurance company, which was launched May 22 under the name Medical Mutual of Cleveland, Inc, and which also provides benefits in case of surgical and obstetric expenses

RHODE ISLAND

Society News—The Providence Medical Association was addressed May 7 by Drs Roland Hammond, Providence on "Hugh Owen Thomas The Apostle of Rest" and Orville T Bailey, Boston, on "The Uses of Purified Human Fibrinogen and Thrombin in Medicine and Surgery"

Meeting on Industrial Health—The New England Conference of the American Association of Industrial Physicians and Surgeons was held at Pawtucket, May 2 Included among the speakers were

Dr John E Donley, Providence, Rehabilitation of Workers Under the Workmen's Compensation Act at the New Curative Center
Dr Ubaldo F Zambarano Wallum Lake, Tuberculosis in Industry
Dr Vincent J Ryan Providence, Industrial Dermatoses—Treatment
Dr Henry B Moor, Providence, Burns and Treatment

SOUTH CAROLINA

Personal—Dr Luther A Riser has resigned as director of the department of vital statistics of the state board of health, Columbia

"Industrialights."—The South Carolina State Board of Health and the division of industrial hygiene are cooperating in the publication of a health news abstract entitled *Industrialights*, which was to appear for the first time in May

Dr. Williams Honored.—A special program was held May 1 honoring Dr Charles F Williams on his retirement as medical superintendent of the South Carolina State Hospital, Columbia, to become director of the hospital's research activities (THE JOURNAL, March 24, p 725) A feature of the occasion was the announcement of a portrait of Dr Williams to be painted by Charles Mason Crowson Dr Williams held the superintendency for thirty years Dr Cort Ham, clinical director at the hospital, is the new superintendent, and Dr. Glenn B Carrigan will succeed Dr. Hoyt in his position

Statewide Tuberculosis Program—The industrial committee of the South Carolina Tuberculosis Association plans to photofluorograph all industrial employees in the state Results will be checked and cooperation will be extended to place employees in sheltered work as well as to assist private physicians in the isolation of infectious cases of tuberculosis The program was adopted from an x-ray survey carried on by the state board of health The program will work through the county health departments and tuberculosis associations and with the full assistance of the consultant nurses of the industrial hygiene division

TENNESSEE

Physician Expands Telephone Service—Dr Leander C Bryan, who owns the Rutledge Telephone Company of Rutledge, has received permission by the state railroad and public utilities commission to enlarge his telephone exchange and install dial telephones The physician entered the telephone business for the convenience of his patients, newspapers reported, and is said to have taken over the exchange because improved service was necessary for his practice His company's 230 miles of line serves 192 subscribers

Fifty Year Practitioners Honored.—Dr William L Howard, Memphis, who has completed fifty years in the practice of medicine, observed the event by giving a dinner recently for his colleagues who have practiced the same length of time Guests at the dinner included Drs Eugene M Holder, Benjamin F Turner, Elmer E Francis, William B Burns, Alfred Moore and Arthur B Williams Two physicians who could not attend because they were out of town were Drs Edward C Ellett and Pope M Farrington All are of Memphis

VIRGINIA

Special Meeting to Discuss Health Education—The health education program now being promoted in a limited number of counties on an experimental basis under the direction of the health and physical education section of the division of instruction, state department of education, was the reason for a special meeting of the council of the Medical Society of Virginia in Richmond, April 6 The state medical journal reported that the program as first presented was all right but that it had not been carried out according to plan and, further, it had been found that it was started before being presented to the council or state health department It had been stated that the medical and hospital services would be financed by civic and community organizations, but it was learned that the parents were being required to pay if they were thought to be financially able One physician at the meeting contended that if a fee is paid by the parent the patient is a private one and should be allowed the selection of his physician It was pointed out at the meeting that the Lynchburg physicians had done no operations nor would they under the present plan and that hospitals had stated that they would be unable to accommodate for hospital care these children under the program One recommendation urged that an announcement be published pointing out that the worker carrying on the educational program was a Ph D and not an M D and stating that the defects found in school children were the result of an examination made by teachers and that therefore many of these defects probably would not be found to be present if examined by competent physicians The meeting resulted in the agreement of the council to appoint a committee to meet with Mr Eliot V Graves, supervisor of physical and health education for the state, to develop a standard and cooperative program A resolution previously adopted by the council was reaffirmed, approving the principle of health education in state schools but disapproving other aspects of the project as carried out in the experimental counties The resolution further approved the examination of school children by competent physicians and the correction of remediable defects The opinion of the council that the project should be supervised by the state health department was carried

WASHINGTON

Hospital Beneficiary on Insurance Policies—The Children's Orthopedic Hospital, Seattle, recently received $156,465 from the Seattle Life Underwriters Association from insurance policies that have been written as a part of a campaign started in 1925 to provide the hospital with an adequate endowment fund Eventually the hospital is to realize $366,232, which would have been $32,492 more had not the hospital been required to pay this amount to keep in force policies of some persons who could not continue to pay premiums The Children's Orthopedic Hospital was founded as a 7 bed ward in the Seattle General Hospital in 1907 by 24 women who pledged $20 each to help the city's crippled children In 1925 the insurance idea was launched and the recent sum of $156,465 was the result of endowments maturing in 1945 A total of $789,771 of insurance was written during a two week campaign More than half of the amount, principally in $500 and $1,000 policies, was kept in force despite the depression, an unusual retention record for bequest insurance, an announcement stated The proceeds of the policies go into the institution's permanent fund and cannot be expended for maintenance or building needs

GENERAL

International Health Organization—A security conference committee in San Francisco on May 28 voted unanimously to support a China-Brazil proposal for an early world conference to form an international health organization, newspapers report

Papaverine Removed from Quota Restrictions—H J Anslinger, commissioner of narcotics, Bureau of Narcotics, Treasury Department, Washington, D C, announces that the increased production of papaverine has so improved the supply situation pertaining to this drug that it can now be removed from quota restrictions Manufacturers and wholesalers may now purchase whatever quantities of the drug are required by them for manufacture or distribution for medical needs, irrespective of any quota limitation heretofore imposed

First Scholarship Awarded in Physical Therapy.—The first scholarship award in the campaign of the National Foundation for Infantile Paralysis to recruit 1,000 persons for physical therapists was made to Miss Marjorie Katherine Ionta, North Weymouth, Mass, during a luncheon meeting at the Waldorf-Astoria, New York, May 25 Miss Ionta will study at Harvard Medical School, Boston This activity will be financed by $1,267,600 earmarked for physical therapy by the National Foundation (THE JOURNAL, March 24, p 727)

Architects Urge Accessibility of Buildings for Cripples—A seven point program to make public buildings easily accessible to handicapped persons, both veterans and civilians, has been proposed by the architects' advisory committee of the National Society for Crippled Children, newspapers report The plan would eliminate outside steps to public buildings and flights of steps by providing grade level entrances It would provide convenient elevator service in all buildings, eliminate inside steps, do away with all excessively high curbs and place hand rails on both sides of steps the full length of flights wherever steps cannot be eliminated

Abbott Laboratories Provides Research Fellowships—The Abbott Laboratories, North Chicago, Ill, has appropriated $50,000 to provide for research fellowships in ten universities Under the terms of the grants, $5,000 has been given each university to support research in the field of medicinal products during a five year period beginning a year after cessation of hostilities The universities are to have the sole right to publish, patent, license or otherwise dispose of the results of the research conducted The grants do not restrict the universities regarding the type or scope of the problem selected within the specified field of research The ten universities and the fellowships to be established in them are California Institute of Technology, Pasadena, Calif, research in physical chemistry and biophysics, Cornell University, Ithaca, N Y, research in bacteriology, Harvard University, Cambridge, Mass, research in pharmacology, University of Illinois College of Medicine, Chicago, research in pharmacology, Massachusetts Institute of Technology, Cambridge, research in organic chemistry, University of Minnesota, Minneapolis, research in biochemistry, Ohio State University, Columbus, research in organic chemistry, Purdue University, Lafayette Ind, research in organic chemistry, Tulane University of Louisiana New Orleans research in chemotherapy and tropical diseases, and the University of Wisconsin, Madison, research in nutritional chemistry

CORRECTION

Rats and Rat Bites—The Current Comment with this title published in THE JOURNAL, June 2, page 367 contains the statement that "almost 25 per cent of the people in a 2 square mile area of Baltimore were bitten by rats over a four year period!" This should have read "Almost 25 people per year in a 2 square mile area of Baltimore were bitten by rats over a four year period!"

The Shortage of Medical Books and Journals

As with all other forms of publication, the medical is in great difficulties as a result of the paper control imposed by the war. In the House of Lords Viscount Buckmaster raised the question of the supply of paper for medical publications. He said that publishers were now unable to supply the basic minimum of books needed by medical students. "Gray's Anatomy" was quite unobtainable. He had tried to get it, either new or second hand, without success. The same applied to "Buchanan's Anatomy" and "Cunningham's Anatomy." In physiology matters, if anything, were worse. In one class of students 15 per cent could not beg, borrow or by any means short of theft obtain a copy of any of the leading works. The physician in practice was in the same trouble. Not merely were writers prevented by shortage of paper from writing books, but there was a shortage of journals. An editor had advised him that he had a waiting list of 1,500 doctors seeking to become subscribers and that he was quite unable to meet the demand for his journal in the liberated countries. Another editor assured him that he could not meet the demands of his subscribers, that his correspondence was drastically cut down and that much medical knowledge of the first importance could not be passed on. The new field of social medicine required every encouragement, but the Ministry of Supply refused to allow the British Medical Association a ton of paper a year to start a *Journal of Social Medicine*.

Replying for the government, the earl of Selborne, minister of economic warfare, said that the government was aware of the immense importance of books, especially at the present time. But although we had more ships than ever before, shipping shortage was greater than ever owing to other demands. We had acquired all the paper we could in America and an addition was not possible. Moreover, every ton of shipping was now required for pursuing the war and for feeding liberated Europe. Paper was not the only bottle neck; labor in the printing and publishing trades was also in short supply. As to medical books, he was advised that their publication at the moment was 80 per cent of that before control. But this was a matter requiring the most serious consideration and he would draw the attention of the president of the board of trade to the remarks made.

The Presidency of the British Medical Association

The British Medical Association has had the misfortune of losing two presidents in the past two years who died while in office: Sir Beckwith Whitehouse and Lord Dawson. The council has appointed Mr. H. S. Souttar, surgeon to the London Hospital, as president until the next annual representative meeting in July and has recommended to the representative body his election as president for the coming year. The new president is a leading surgeon in active practice and has held a succession of high offices in the association. In 1934-1937 he was chairman of the representative body. He was chairman of the council during the first four years of the war, of the Central Medical War Committee and of the Medical Planning Commission.

Medical Students for German Concentration Camp

The official report on the conditions in the German concentration camps for political prisoners which have been captured by the Americans have horrified the British public. To help in the treatment of cases of starvation 95 senior medical students from the London hospitals have been sent to Belsen camp under the auspices of the Red Cross. The students volunteered in response to a call from the Ministry of Health. They will operate in teams of 12 under the guidance of experts from the Ministry of Health and Ministry of Food and under the direction of the Civil Affairs Branch of the British Armies of Liberation. At Belsen concentration camp six civilian teams are already workering. Five are manned by members of the Red Cross and the sixth is a relief team of the Society of Friends. Each team consists of 12 men and women and is self supporting, carrying its own cooking and washing apparatus and its own stores and equipment. Two ambulances, two trucks and a 3 ton lorry are attached to each team.

Health Conditions in France

The minister of public health, who is the guardian of the health of the nation, has given to the consultative assembly serious evidences on the health conditions in the country. The figures and comments concern not only the physical status of the population, with impressive demographic statistics, but also the moral status created by the years of war and suffering. For instance, 37,000 children have been abandoned, compared to 20,000 in 1936; the number of delinquent children has advanced during the same period from 12,000 to 36,000; the assistance organizations at present have in their charge more than 200,000 minors but are far from having sufficient resources and equipment necessary to accomplish this hard task.

Infant mortality has increased 40 per cent; cases of typhoid have doubled, those of diphtheria have tripled; cases of tuberculosis have increased by about 11 per cent on the average, but in Paris by 48 per cent and at the mouth of the Rhone (Marseilles) by 74 per cent.

In 1943 there were 64,000 deaths from tuberculosis, a figure certainly lower than it is in reality, particularly since the deaths are often declared under other causes than tuberculosis. For the ages between 20 and 40 years, more than 40 per cent of the deaths are due to tuberculosis and for the women of this age, which is that of maternity, it is 49 per cent. This is different from cancer, which kills 10 per cent of women but mostly those over 40. This shows what influence the tuberculosis mortality can have on the birth rate. According to Moine, statistician of the Comité national of the campaign against tuberculosis, this disease has killed 4 million in France since 1900, of which number 1½ million would have been alive today, a figure which would add to the population yet another million of the children they would have had. If France had only had the tuberculosis mortality of Great Britain, its population today would be 600,000 more. The tuberculosis mortality in France remains at 137 per hundred thousand inhabitants in contrast with 48 in the Netherlands, 54 in the United States and 71 in Great Britain. It has decreased in all countries by 66 since the beginning of the century: 66 per cent in the United States, in the Netherlands and Germany, 55 per cent in Great Britain and only 39 and 38 in Italy and France.

Three different periods during the war can be differentiated: from September 1939 to the winter of 1940; 1941 and 1942, and 1943 and 1944. The first period which followed the declaration of war presents nothing unusual, but beginning with the summer of 1940 one observed a noteworthy increase in the cases registered by the insurance organizations. The seriousness of 20 per cent of these cases became alarming. The miliary and meningitic forms multipled; the rapidly fatal developments advanced from 15 per cent in 1937 to 45 per cent. The fatal extrapulmonary localizations, bilateralization and relapses were seen more frequently. During the third period the serious forms became less frequent and the mortality decreased. It seems that there had been a sort of epi-

demic of serious tuberculosis; all those who did not have sufficient resistance having been decimated, the surving ones were less vulnerable. But it is now already certain that the mortality figures of tuberculosis in France for the years to come will be above all those recorded up to now.

Criminal Abortion

According to Dérobert of the Société de médecine légale de France, in 1938 it was estimated that 500,000 criminal abortions were practiced in France; that is to say, a figure much greater than that of living births. Dérobert affirms that this figure of 500,000 is greatly exceeded at present. Meanwhile the legislator has not ceased to increase legal action against this national scourge, either by repressive measures or by arrangements such as the pardon for informers, the dispensation from professional secrecy, the supervision of maternity homes and so on. However, the evolution of repression is "a series of capitulations."

Sociologists as well as physicians have hoped to conquer the scourge by repression rather than by prevention. Criminal abortion depends on two types of factors, moral and pecuniary. The one or the other predominates, depending on the environment. In former times the moral factor was principally the dishonor of being an unmarried mother; at present it consists above all in the selfishness and the amorality of the prospective mother and her surroundings. This degradation in individual and social morality goes parallel with the weakening of religious morality, which lives or sleeps in every soul.

However, it is necessary to consider the pecuniary factors. The child who is born in France in our days is a heavy burden and a considerable encumbrance. The first born is accepted, but the others are undesirable. Statistics set up by social insurances show that 66 per cent of women who abort have only one child. France is the country of the family with one child. The second one costs too dear and creates too many difficulties in a country where everything is missing.

Certainly there are fiscal privileges and special allocations for large families, but they hardly count for one or two children; they increase only slightly for a family of three children; they are far from compensating for the increase in expenses which the children cause.

Food Rationing in France After the War

Based on the general forms of human food allowance fixed by the League of Nations in 1936 and 1938, Simonnet of the Institut national d'hygiène has tried to establish the food ration suitable for the French after the war. He has adapted theoretical information to the various realities: resources of the nation, former habits, climatic conditions and nutritional needs created by the state of malnutrition resulting from the war. He has also taken account of the correlations between nutrition and the morbidity in various diseases and the needs of certain groups of the population.

The work of Simonnet consists of four parts: (1) the determination of energy producing foods, (2) the determination of the protein requirements, (3) the determination of the mineral and vitamin requirements and their transposition in protective foods and finally (4) the estimation of fat and carbohydrate requirements.

He arrives at two conclusions: 1. The per capita consumption without taking into account the age, the occupation and the pathologic or physiologic status. 2. The establishment of a scale of coefficients applicable to every category of the total population.

The energy producing needs correspond to the sum of several elements: the caloric needs of the basal metabolism, the specific dynamic action of the foods, the thermoregulation, the muscular and digestive work, growth and, in pregnant women or young mothers, the requirements of gestation and lactation. On the other hand, the environment in which the person lives, his present state of nutrition, his age, sex and muscular activity may modify the average figures. The specific dynamic action varies according to the nature of the foods ingested and according to their combination. The thermoregulation is influenced by the work, the clothing and the external temperature. Muscular work varies greatly, as do also the requirements of growth. A careful study arrives at a figure between 2,400 and 2,750 calories for twenty-four hours for a person weighing about 143 pounds (65 Kg.).

Reliable statistics indicate for the usual consumption of a person in France before the war an average of 3,000 calories. The soldier, for instance, receives a ration of from 2,926 to 3,434 calories. In a large insane asylum the ration was 2,800 calories. Richet has evaluated the intake of a Parisian before the war at 3,278 calories. In 1943 the allowance was only from 1,500 to 1,800 calories according to the categories of consumers; the Germans had decided that the French ate too much. Moreover, it should not be forgotten that the French food allowance was terribly unbalanced, which complicates the study of its effect on the disturbances of malnutrition observed since 1939.

The fats should account in the diet of tomorrow for about 46 Gm. and the carbohydrates for 400 to 450 Gm.

The theoretical ration of the French will be established at around 2,800 calories, provided by 100 Gm. of proteins, of vegetable and animal origin in equal parts, 420 Gm. of carbohydrates and 60 to 80 Gm. of fats.

Pressure in the Right Ventricle

Lenègre and Maurice communicated to the Société de cardiologie their first investigations on the pressure in the right ventricle. They introduce through an arm vein and into the right ventricle a semisoft catheter of small caliber that is connected with a Claude manometer. The pressure observed in normal subjects was between 10 and 20 cm.; it is slightly higher in adults than in young subjects. In 37 patients with cardiac disorders figures as high as 60 were reached; the mean was 31. Thus between healthy subjects and those with heart disease differences of as much as 1 to 5 may exist; that is to say, the differences are much greater than those encountered in the systemic circulation. The ventricular pressure attains its maximum in grave mitral valvulitis with cardiac insufficiency or pulmonary complications. It was also ascertained that the intraventricular pressure is higher in the reclining than in the upright posture; this may explain the dyspneas of the reclining position, which are so distressing in the course of ventricular syncopes.

Marriages

JUDSON ALBERT MILLSPAUGH, Lieutenant Commander (MC), U. S. Navy, to Miss Ellen Ann Huskes in Hollywood-in-Florida, April 9.

GUY PARRY YOUMANS, Chicago, to Miss Anne Louise Stewart of Springfield, Mo., in Winnetka, Ill., March 17.

JACK M. STEMPER to Miss Dorothy Mae Campbell, both of Kansas City, Mo., in Kansas City, Kan., March 10.

WILLIAM CHARLES RUCKER to DR. VENDELA EVELYN OLSON, both of Hackensack, N. J., April 28.

SIEGFRIED R. BERTHELSDORF, Olene, Ore., to Miss Mildred Freiderich of Tampa, Fla., May 13.

ROBERT LANCEFIELD THOMAS, to Miss Gladys Margery Watt, both of Berkeley, Calif., April 28.

MICHAEL V. GUALTIERI to Miss Shirley Margaret Lawson, both of Waterbury, Conn, May 5.

WILLIAM LE GRAND HOON, Prospect, Pa., to Miss Anna M. Tyrrell of Merion, Pa., March 29.

ALBERT GAYLAND YOUNG, Boston, to Miss Mary A. Kennedy of Rochdale, Mass., April 7.

Deaths

Oliver James Fay ⊕ died at the Iowa Methodist Hospital, Des Moines, June 2, of arteriosclerosis and myocardial failure, aged 70.

Dr. Fay was born in Pottsville, Iowa, July 2, 1874. He received his B.S. degree at the Iowa State College in 1898 and graduated at the College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, in 1902, serving his internship at Augustana Hospital, Chicago. In 1904 he returned to Des Moines to specialize in surgery. Subsequently he became a charter member of the American College of Surgeons and a founder member of the American Board of Surgery. He had served as president of the Polk County Medical Society and of the Iowa State Medical Society, holding membership on the latter's board of trustees since 1924. He had also been president of the Northwest Conference for Medical Service. Included among the groups in which he also held membership are the Western Surgical Association, the American Association of Railway Surgeons and the American Association of Industrial Physicians and Surgeons. He was a member of the staff of the Iowa Methodist Hospital and a consultant to the Broadlawns General Hospital, chief district surgeon for the Rock Island Railroad, consultant surgeon for the Burlington and Northwestern railroads and retired medical director of the Northwestern Bell Telephone Company.

Dr. Fay had been medical director of the Iowa State Industrial Commission since its inception in 1913; in 1933 he was one of nine members of a committee specially appointed by the legislature to investigate the causes and suggest remedies for the waiting list of indigent patients committed but not admitted to the University Hospitals, Iowa City.

One of Dr. Fay's chief interests was the acquisition of a medical as well as a comprehensive general library. In 1940 he donated his own private collection of some 1,500 volumes to found the medical library at the Iowa Methodist Hospital.

Max Winsor ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1932; member of the American Orthopsychiatric Association; educational director of the Amalgamated Clothing Workers Union from 1922 to 1924, and from 1926 to 1931 engaged in the study of penal institutions in the United States and psychologic studies of one hundred leading criminals for the Rockefeller Foundation; from 1932 to 1937 initiated liaison between the Neurological and Psychiatric Institute of the Columbia Presbyterian Medical Center and the New York State Training School for Boys to provide medical and psychiatric treatment for delinquent boys; administered this program at the New York Training School for Boys at Warwick, N. Y., where he was a resident in the medical center unit; in 1937 established the first clinic for psychiatric treatment in the Children's Court in New York City; in 1938 appointed to the bureau of child guidance of the city board of education as psychiatrist in charge of the Harlem area; beginning in 1940 the New York School of Social Work of Columbia University established a teaching unit under his direction for psychiatric social work majors; in September 1943 named director of clinical work in a two year research project sponsored by the New York Foundation and the board of education; in the summer of 1944 appointed to the staff of the New York School of Social work as lecturer in social psychiatry; vice chairman of the citywide citizens' committee for Harlem and served as chairman of its subcommittee on delinquency; a member of the board of Wiltwyck School and of the advisory committee of the Treatment Clinic of the Domestic Relations Court; died in the Beth Israel Hospital May 4, aged 47, of coronary heart disease.

Maurice Holmes Rees ⊕ Denver; Washington University School of Medicine, St. Louis, 1921; since 1925 dean and since 1921 professor of physiology and pharmacology at the University of Colorado School of Medicine, where during 1924-1925 he served as assistant dean; fellow in zoology at the University of Illinois, 1904-1905; professor of science at the York (Neb.) College, 1905-1906; professor of biology at the Tarkio (Mo.) College from 1906 to 1914; assistant professor of physiology at the University of Kansas from 1914 to 1916; associate in physiology at the University of Chicago, 1916-1917; professor of physiology at the University of South Dakota from 1917 to 1921; chairman of the Section on Pathology and Physiology of the American Medical Association, 1928-1929; member and formerly chairman of the executive council of the Association of American Medical Colleges, of which he had been president and vice president; had been active in that organization for several years; elected vice president of the Advisory Council on Medical Education at its formation in 1939; past president of the Denver Public Health Council; fellow of the American College of Hospital Administrators; in 1941 elected to membership in the National Board of Medical Examiners, serving as chairman of the subsidiary board of Denver; member of the American Physiological Society and the Denver Clinical and Pathological Society; in 1932 chairman of the medical service division of the Colorado White House Conference on Child Health and Protection in Denver; superintendent of the Colorado General Hospital; died May 25, aged 62, of coronary occlusion.

William Anthony Mulherin ⊕ Augusta, Ga.; Harvard Medical School, Boston, 1901; emeritus professor of clinical pediatrics at the University of Georgia School of Medicine; member of the House of Delegates of the American Medical Association in 1942, 1943 and 1944, and vice chairman of the Section on Diseases of Children in 1921, serving as chairman of the section in 1928-1929; in 1922 appointed a member of the Abraham Jacobi Committee of the section and later a member of a committee to study teaching of pediatrics in American universities and report to the section with suggestions as to betterments; fellow of the American Academy of Pediatrics; one of five to organize the pediatric section of the Southern Medical Association, serving as secretary of the section in 1919 and chairman in 1920; member of the American Pediatric Society; past president of the Medical Association of Georgia; served as a member of the state board of health and as chairman of the Richmond County Board of Health; dean emeritus of the Southern Pediatric Seminar, which he organized; organized pediatric societies in various localities; served as a member of President Hoover's Conference on Child Health and Protection; on the staffs of the University and Children's hospitals; received the honorary doctor of science from the University of Georgia in 1929; died in his sleep April 19, aged 72, of coronary thrombosis.

Joseph Byrne, New York; College of Physicians and Surgeons, New York, 1895; formerly dean and professor of neurology at the Fordham University School of Medicine; veteran of the Spanish-American War; past president of the medical board of the Central and Neurological Hospital on Welfare Island; had long been a consultant to the City, Fordham and Neurological hospitals; served as a member of the advisory board of the city health department; fellow of the New York Academy of Medicine; member of the Royal College of Surgeons of England, Society for Experimental Biology and Medicine, New York Neurological Association and the Alumni Association of the College of Physicians and Surgeons; received the bachelor of laws degree from the New York Law School in 1900 and the degree doctor of laws from the Fordham University in 1921; author of numerous books; had made extensive experimental and clinical studies on the mechanism of sensation and contributed numerous articles to the literature; died May 13, aged 75, of cardiac asthma.

Howard Elmer Ashbury ⊕ Baltimore; University of Maryland School of Medicine, Baltimore, 1903; also a pharmacist; specialist certified by the American Board of Radiology, Inc.; member of the American Roentgen Ray Society and the American College of Radiology; for many years assistant in surgery and orthopedic surgery at the Johns Hopkins University School of Medicine and Hospital; during World War I a major in the medical corps of the U. S. Army, serving as professor of roentgenology at the Army Medical School, as inspector of the roentgenologic service of the Eastern department and as chief of the x-ray laboratory of the U. S. Army; relieved from active duty as a lieutenant colonel in the medical corps of the Army of the United States in February 1944; consultant roentgenologist for the U. S. Veterans Bureau; roentgenologist at St. Joseph and Provident hospitals; consultant on the staff of the Waynesboro (Pa.) Hospital; died February 20, aged 64.

Hiram N. Vineberg ⊕ New York; McGill University Faculty of Medicine, [illegible] Canada, 1878; in 1918 president of the New [illegible]ty and in 1926 a vice president of the [illegible] Society; fellow of the American Colleg[illegible] appointed chief of staff in the outpatient department of Mount Sinai Hospital, where he had been ever since, having been appointed consulting gynecologist on his retirement in 1921; in June 1943 was presented by his colleagues with a special volume of scientific writings to mark his completion of sixty-five years in the practice of medicine; the gift consisted of a three hundred and sixty page issue of the Journal of the Mount Sinai Hospital; associated at various periods with the Polyclinic, St. Mark's and Post-Graduate hospitals and the Montefiore Home for Chronic Invalids; for many years gynecologist in chief at Beth Moses Hospital; died May 4, aged 87.

George Mason Creevey ⊕ New Hartford, Conn.; Columbia University College of Physicians and Surgeons, New York, 1896; an Affiliate Fellow of the American Medical Association; member of the Medical Society of the State of New York, American Society of Anesthetists, International Anesthesia Research Society and the International College of Anesthesia; specialist certified by the American Board of Anesthesiology, Inc.; formerly chairman of the anesthesia committee of the Doctors Hospital, consulting anesthetist, Flower-Fifth Avenue Hospitals, New York Eye and Ear Infirmary and New York Orthopedic Dispensary and Hospital all in New York; died April 30, aged 72, of coronary occlusion.

Charles Eugene Ferguson, Indianapolis; Medical College of Indiana, Indianapolis, 1892; professor emeritus of obstetrics at the Indiana University School of Medicine; at one time secretary of the city board of health; past president of the Indianapolis Medical Society and the Indianapolis Literary Society; fellow of the American College of Surgeons; member of the consulting staff and formerly superintendent of the Indianapolis City Hospital; served as superintendent of the City Dispensary; consultant, Robert W. Long Hospital; formerly on the staffs of the City Hospital, St. Vincent's Hospital and the Methodist Hospital, where he died May 18, aged 88, of cerebral hemorrhage.

Louis Joseph Burns, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1900; associate professor of laryngology at the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania; member of the American Medical Association, the American Academy of Ophthalmology and Otolaryngology and the American Laryngological, Rhinological and Otological Society; life member of the Philadelphia Laryngological Society; specialist certified by the American Board of Otolaryngology; on the staff of the Philadelphia General Hospital; died May 20, aged 70.

Thomas Ambrose Bray, Holliston, Mass.; Georgetown University School of Medicine, Washington, D. C., 1922; member of the American Medical Association; interned at the Central Dispensary and Emergency Hospital in Washington, D. C., and St. Francis Hospital in New York; served a residency at the New York Eye and Ear Infirmary in New York; formerly on the staff of St. Vincent Hospital in Worcester; on the staffs of the Framingham (Mass.) Union and Milford (Mass.) hospitals; died April 1, aged 50, of acute myocardial failure.

Robert Swan Alston ⊕ Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1917; fellow of the American College of Surgeons; served during World War I; surgeon at the Stetson Hospital; chief of service in general surgery at the Germantown Hospital, where he died April 24, aged 52, of coronary thrombosis.

Edmund Kent Ayling ⊕ South Bend, Ind.; Northwestern University Medical School, Chicago, 1903; died in St. Joseph Hospital April 25, aged 74, of pneumonia.

George Henry Benton, Coconut Grove, Fla.; Metropolitan Medical College, Chicago, 1899; died in a hospital at Miami March 24, aged 77, of cerebral hemorrhage, hypertension and coronary artery disease.

James Henry Boulware, Zanesville, Ohio; Leonard Medical College, Raleigh, N. C., 1911; member of the American Medical Association; city prison physician; on the staffs of Bethesda Hospital and the Good Samaritan Hospital, where he died April 30, aged 63, of coronary occlusion.

Albert William Bouseman, Fountain Green, Ill.; Barnes Medical College, St. Louis, 1910; found dead about 3 miles southwest of La Harpe April 15, aged 64, of heart disease.

Gilbert Freck Bretz, Pottsville, Pa.; Jefferson Medical College of Philadelphia, 1914; member of the American Medical Association; treasurer of the Schuylkill County Medical Society; on the staff of the Lemos B. Warne Hospital, where he died April 14, aged 70, of occlusion of cerebral blood vessels and generalized arteriosclerosis.

Matthew Gardner Buckner ⊕ Nashville, Tenn.; University of Nashville Medical Department, 1896; served during World War I; for many years president of the Y. M. C. A.; died April 10, aged 74, of acute nephritis.

James Pettigrew Bunn ⊕ Rocky Mount, N. C.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1935; secretary treasurer of the Edgecombe-Nash Counties Medical Society; past president of the Lions Club; on the staff of the Park View Hospital; part owner of the Speight-Stone-Bunn Clinic Hospital, where he died April 5, aged 35.

C. Dana Carter ⊕ Thermopolis, Wyo.; Missouri Medical College, St. Louis, 1895; county health officer and city physician; physician and surgeon for the Chicago, Burlington and Quincy Railroad; county welfare physician; examiner for the Selective Service; for many years owner of the Carter Hospital; died March 20, aged 71, of cardiac failure.

Franklin Harvick Carter ⊕ San Diego, Calif.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1911; died April 13, aged 57, of tuberculosis.

Raymond Carlton Clapp Sr., Wichita, Kan.; University of Louisville Medical Department, Louisville, Ky., 1907; died April 20, aged 64.

Charles Ely Coleman, Belleville, Ill.; Bennett Medical College, Chicago, 1914; died April 8, aged 73.

John R. Colson, Schell City, Mo.; University Medical College of Kansas City, 1890; member of the American Medical Association; died in the Nevada Hospital, Nevada, April 14, aged 80, of pernicious anemia.

Artice Edward Culberson ⊕ Anniston, Ala.; Birmingham Medical College, 1915; health officer of Calhoun County and city physician; served in France during World War I and as team physician for the athletic organizations at the Anniston High School; on the staff of the Anniston Memorial Hospital, where he died May 1, aged 52, of carcinoma of the stomach.

Edward Thomas Curran, Brooklyn; Long Island College Hospital, Brooklyn, 1905; also a lawyer; veteran of the Spanish-American War and of the Boxer and Philippine rebellions; died March 28, aged 73.

Gilbert Alexander Daniel ⊕ Belle, W. Va.; Medical College of Virginia, Richmond, 1926; died April 20, aged 42.

John McCamie De Armon, Charlotte, N. C.; University of Maryland School of Medicine, Baltimore, 1886; member of the American Medical Association; honorary member of the Medical Society of the State of North Carolina; past president of the Mecklenburg County Medical Society; died in the Mercy Hospital April 22, aged 87, of acute dilatation of the heart.

Charles E. Dorr, Worden, Ill.; Marion-Sims Beaumont Medical College, St. Louis, 1903; member of the American Medical Association; on the staff of the St. Francis Hospital at Litchfield; died April 20, aged 64, of angina pectoris.

William Lincoln Downing, Moulton, Iowa; Rush Medical College, Chicago, 1886; member of the American Medical Association; died April 16, aged 83.

Albert C. Earnest, Wheeling, W. Va.; Hospital College of Medicine, Louisville, Ky., 1896; member of the American Medical Association; retired medical examiner for the Baltimore and Ohio Railroad; died April 29, aged 73, of pulmonary tuberculosis.

Logan Felts, Russellville, Ky.; Kentucky University Medical Department, Louisville, 1905; member of the American Medical Association; served overseas during World War I; died April 18, aged 62, of coronary occlusion.

Sidney LaSalle Ford, Hensonville, N. Y.; University of the City of New York Medical Department, New York, 1891; member of the American Medical Association; at one time chairman of the Green County Board of Supervisors; health officer of the towns of Windham and Jewett; died in the Memorial Hospital, Catskill, April 16, aged 80, of coronary thrombosis.

Charles E. Freeman ⊕ Colonel, U. S. Army, retired, San Antonio, Texas; Barnes Medical College, St. Louis, 1899; Army Medical School, 1906; entered the U. S. Army as an assistant surgeon in 1906; served during World War I; promoted through the various grades to that of colonel in 1932; retired on Aug. 31, 1937 by operation of law; died in the Brooke General Hospital, Nov. 19, 1944, aged 71, of coronary heart disease.

Frederick J. Freshley, Evansville, Ind.; University of Louisville Medical Department, Louisville, Ky., 1908; died April 8, aged 60, of pulmonary tuberculosis.

Obe C. Gibson, Tampa, Fla.; Louisville (Ky.) Medical College, 1884; died April 22, aged 81, of cardiac collapse with hypertension.

John Fordyce Gruber ⊕ Cadillac, Mich.; Saginaw Valley Medical College, Saginaw, 1902; county coroner; served overseas during World War I; on the staff of the Mercy Hospital; died April 18, aged 63, of carcinoma of the small bowel.

Richard Emerson Herring, Arlington, Tenn.; Memphis Hospital Medical College, 1903; died April 15, aged 70, of sulcus tumor of the lung.

John Thomas Herron, Jackson, Tenn.; Jefferson Medical College of Philadelphia, 1884; honorary member of the Tennessee State Medical Association; member of the American Medical Association and served as a delegate from Tennessee in 1904-1905; died in the Memorial Hospital April 21, aged 85, of senility.

Frederick William Hodgins ⊕ Oakland, Calif.; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1896; died April 6, aged 71, of generalized arteriosclerosis.

Isaac Jones Hoover ⊕ Owensboro, Kv.; Hospital College of Medicine, Louisville, 1907; member of the Southeastern Surgical Congress; fellow of the American College of Surgeons; past president of the Daviess County Medical Society; served during World War I; on the staff of the Owensboro-Daviess County Hospital, where he died April 22, aged 63, of cardiovascular disease.

William Thorpe Hopkins ⊕ Lynn, Mass.; Boston University School of Medicine, 1890; an Affiliate Fellow of the American Medical Association; fellow of the American College of Surgeons; formerly health commissioner of Lynn; on the staff of the Lynn Hospital; died April 10, aged 76, of arteriosclerotic heart disease.

Roy Howe ⊕ Daytona Beach, Fla.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1905; served during World War I; on the staff of the Halifax District Hospital; died in the Veterans Administration Facility, Lake City, May 3, aged 69, of cancer of the gallbladder.

Charles Stowell Hunter, West Sunbury, Pa.; Medical Department of the Western University of Pennsylvania, Pittsburgh, 1904; member of the American Medical Association; on the staff of the Butler County Memorial Hospital, Butler, where he died April 5, aged 69, of coronary occlusion and pulmonary embolism.

Alvin Keller, Bloomington, Ill.; Rush Medical College, Chicago, 1901; died in the Alta Bates Hospital, Berkeley, April 6, of coronary thrombosis.

Capt. Orrin Fluhr Crankshaw
M. C., A. U. S., 1910-1945

Albert Charles Lamade ⊕ Williamsport, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1901; a captain in the medical corps of the U. S. Army, stationed at Camp Wadsworth, during World War I; died April 13, aged 67, of cerebral hemorrhage.

William Sterling Langfitt ⊕ Pittsburgh; Medical Department of the Western University of Pennsylvania, Pittsburgh, 1894; fellow of the American College of Surgeons; with his father founded St. John's General Hospital, where he had been director and for many years chief of the surgical staff; died April 16, aged 72, of cerebral arteriosclerosis.

John Wesley Milam, Nashville, Tenn.; Vanderbilt University School of Medicine, Nashville, 1894; died in the Nashville General Hospital April 9, aged 79, following a prostatectomy.

Floyd Palmer ⊕ Glens Falls, N. Y.; University and Bellevue Hospital Medical College, New York, 1899; coroner of Warren County; a captain with the American Expeditionary Forces during World War I; on the staff of the Glens Falls Hospital; died March 27, aged 71.

Laura Margaret Preble, Old Town, Maine; Woman's Medical College of Pennsylvania, Philadelphia, 1908; died in a hospital at Bangor February 24, aged 76.

Edward Augustine Quinlan, Port Chester, N. Y.; Albany (N. Y.) Medical College, 1898; a member of the staff of the Ladies Hospital and its successor, the United Hospital, where he remained an active member of the staff until 1942, when he retired; at one time in charge of the Nurses Training School of the institution; died March 16, aged 69.

James William Sparks ⊕ Kansas City, Kan.; Kansas City (Mo.) Hahnemann Medical College, 1907; past president of the Wyandotte County Medical Society; on the staffs of the Providence Hospital and the Bethany Hospital, where he died April 9, aged 67, of hemolytic Staphylococcus aureus blood stream infection.

Capt. Arthur Robert Gersabeck
M. C., A. U. S., 1906-1944

Charles Edward Terry, Wingdale, N. Y.; University of Maryland School of Medicine, Baltimore, 1903; health officer of Jacksonville, Fla., from 1910 to 1917; served as health officer for Harlem Valley State Hospital, where he died February 18, aged 67, of cerebral arteriosclerosis.

Joseph Paul Traynor ⊕ Medical Director, Captain, U.S.N., retired, Biddeford, Maine; Medical School of Maine, Portland, 1901; fellow of the American College of Surgeons and of the American College of Physicians; entered the U. S. Navy on May 15, 1902 and retired on June 10, 1928 for incapacity resulting from an incident of the service; died in Scarboro Sept. 12, 1944, aged 66, of coronary occlusion.

Christian Walkonig, Atlanta, Ga.; College of Physicians and Surgeons, Baltimore, 1902; at one time assistant in clinical laboratory at his alma mater; died April 13, aged 66, of cirrhosis of the liver.

KILLED IN ACTION

Orrin Fluhr Crankshaw, Summit, N. J.; Cornell University Medical College, New York, 1935; member of the American Medical Association; served an internship and residency at the New Haven Hospital in New Haven, Conn., where he had been an instructor in the department of internal medicine at the Yale University School of Medicine; served as attending physician for the Bell Telephone Laboratories at Murray Hill and on the staff of the Overlook Hospital; began active duty as a captain in the medical corps, Army of the United States, on July 15, 1942; went abroad with the Yale Medical Unit in November 1942 and later transferred to the medical corps; participated in the battle of Guadalcanal; after returning to this country was sent to England in February 1944; awarded the Bronze Star and Purple Heart for treating injured soldiers under heavy enemy fire after he himself was wounded; attached to the Sixth Armored Division; killed in action in Germany February 23, aged 34.

Arthur Robert Gersabeck, Ypsilanti, Mich.; University of Michigan Medical School, Ann Arbor, 1938; interned at the West Suburban Hospital in Oak Park, Ill.; member of the American Medical Association and the West Virginia Medical Association; entered the medical corps, Army of the United States, on July 20, 1942 as a first lieutenant; began active duty as a captain on Aug. 21, 1942; killed in the European area Dec. 18, 1944, aged 38.

"THE EXPANDING SCOPE OF PUBLIC HEALTH LABORATORIES"

To the Editor:—In the March issue of the *American Journal of Public Health* there appeared an article entitled "The Expanding Scope of Public Health Laboratories," outlining a plan developed in Montgomery County, N. Y., whereby "an approved county laboratory, supported entirely by state and county funds, provides as a free public service for a population of 70,000 people not only the usual diagnostic and sanitary services but also all the medical tests which in most other communities are the task of hospital and private pathological laboratories. This includes all autopsies, surgical pathology, hematology, serology, blood grouping, urinalysis, chemistry of blood and other body fluids, bacteriology, bacterial and agglutination tests, preparation of bacterial vaccines, gastric analysis, basal metabolism, examination of feces and exudates."

In the article the plan is commended on the basis (1) that the centralization of all types of medical and public health laboratory work in one organization eliminates a good deal of duplication and makes better use of plant, apparatus and personnel and (2) that as a consequence of this it is possible to give a small community adequate laboratory service when the amount of work would not be sufficient to support several different hospital, public health and private laboratories.

As chairman of the Committee on Education and Publicity of the American Society of Clinical Pathologists, I have been instructed to call your attention to a situation which is fraught with a great deal of potential danger to the practice of laboratory medicine in particular and perhaps also to that of independent medical practice in general. As the pathologist of an approved hospital laboratory in this state and hence as one who knows from first hand experience the excellent service rendered by the New York State Department of Health Laboratories under the indefatigable efforts and vision of Dr. Augustus Wadsworth, recently retired, I can attest to the valuable progress this group has made in service both to the community and to organized laboratory medicine in the field of public health for the past twenty-five years. However, it would seem to me that in their enthusiasm to enlarge the usefulness of laboratory service to the community by including free laboratory service not directly concerned with public health, as is the case in the plan adopted by Montgomery County, they run a distinct risk of defeating the very ends they desire to attain by any such approach as is outlined in the article. Such a system if put into practice throughout the state and perhaps also in other states would, in my opinion, seriously jeopardize the healthy and natural development that laboratory medicine is now enjoying. It would first of all limit the freedom of choice of the younger pathologist and would tend to force him into seeking state laboratory appointments as the only means of professional and economic development. It would also place at a serious economic disadvantage those private pathologists who work in proprietary hospitals or have laboratories of their own and who engage in outside practice as do other specialists in medicine. These two things to my mind would be serious deterrents to the entry into the specialty of pathology by younger men who might be so inclined. In respect to the public also it would tend to weaken the value of pathologic services, on the basis that something free is not necessarily valuable. It might be harmful also to organized medicine in that, if such a plan by chance should become acceptable to the public, attempts might be made to offer the services of other medical specialists on the same basis to the community.

I should like to make it clear that it is the wish of the American Society of Clinical Pathologists to see a more widespread distribution of laboratory service to the individual community, a point on which the Health Department of New York State concurs; but we seriously question the wisdom of the present approach in recommending that such service be dispensed as a free one to the public. It would seem to us that, with the admitted agreement on a common objective on the part of both the pathologists and the public health agencies in the state and the country at large, the matter might lend itself to a better solution if it was approached jointly by representatives of both groups, motivated by a sincere desire to give an all inclusive modern laboratory service to communities, on a basis of individual community needs and not as is recommended in the Montgomery County Plan, as an overall free public service.

THEODORE J. CURPHEY, M.D., Hempstead, N. Y.

"CHRONIC TOXICITY OF ERGOT"

To the Editor:—In your editorial of April 21 on "Chronic Toxicity of Ergot" you state that "there has been no thorough investigation of the chronic effects of ergot in laboratory animals." The paper by Fitzhugh, Nelson and Calvery (*J. Pharmacol. & Exper. Therap.* **82**:364 [Dec.] 1944) which you quote at length referred only to my first communication in the *American Journal of Pathology* (**6**:299 [May] 1930). I have published additional observations on experimental chronic ergot poisoning in the *Archives of Internal Medicine* (**47**:548 [April] 1931) and in the *Archives of Surgery* (**25**:1135 [Dec.] 1932). Although my first paper described the morbid anatomy of experimental ergot poisoning in 28 roosters, Fitzhugh and his collaborators quote only my observations on 2 animals. These I submitted at length only because the lesions were most typical. In my experiments I obtained lesions of the vessels, particularly of the comb, that were significant. There was intimal proliferation, frequently associated with thrombosis. In some instances there was canalization of the thrombus. Sclerotic and hyaline degeneration of the vascular walls were common findings. The vascular changes resembled closely those observed in thromboangiitis obliterans. There were also trophic changes in the skin, muscles and fasciae supplied by the affected vessels that resembled lesions observed in scleroderma and dermatomyositis. In some instances gangrene of the comb occurred and in 1 animal an esophageal fistula, the result of necrosis. Fitzhugh and his collaborators were not able to produce any vascular changes in rats as a result of ergot feeding. In my original paper I also reported that I was unable to produce vascular lesions in rats, mice, rabbits and guinea pigs by ergot feeding. Feeding with 5 per cent ergot produced no toxic effect. The animals abstained from eating a 10 per cent mixture of ergot because it was distasteful. Ergotism, however, has been produced in rats. McGrath (*Arch. Int. Med.* **55**:942 [June] 1935) injected ergotamine tartrate in doses of 25 to 100 *mg.* per kilogram of body weight and obtained vascular lesions similar to those I reported, including thrombophlebitis, which incidentally also occurs in human ergotism. The trophic changes in his rats arose chiefly in the tails, which became gangrenous, with a line of demarcation occurring in from sixteen to twenty days. It is well to compare McGrath's doses of ergotamine tartrate toxic for rats to the doses of 9.5 to 117 mg. per 50 to 100 Kg. weight, which have been found very toxic in human beings. It is obvious that the rats are far more resistant. This may account for our inability to obtain vascular lesions in these animals by feeding. McGrath also investigated the greater susceptibility of males to ergotism, a fact I had stressed in the resemblance of this condition to thromboangiitis obliterans. With the administration of estrogens he was able to prevent gangrene in the females and retard it in the males after the administration of ergotamine tartrate.

In 1935 Sir Thomas Lewis (*Clin. Sc.* **2**:43 [Sept.] 1935) noted necrosis of the combs in fowl which he had injected

with ergotoxin The necrosis he ascribed to a stasis resulting from the combination of a constriction of the arteries with dilatation of their capillaries This mechanism for the necrosis I reported in my second publication on ergotism in 1931

JULIUS KAUNITZ, M D, New York

To the Editor —Apropos the editorial "Chronic Toxicity of Ergot" appearing in THE JOURNAL, April 21, may I suggest that you supplement your comments on the effect in animals by calling attention to a report in the *American Journal of Veterinary Research* for April 1945 The article on page 107, "Ergotism in Pregnant Sows, Female Rats and Guinea Pigs" will be a revelation

GEORGE F FASTING, M D, New Orleans

DIAGNOSIS OF HERNIATION OF LUMBAR INTERVERTEBRAL DISKS

To the Editor —Dr Keegan (Diagnosis of Herniation of Lumbar Intervertebral Disks by Neurologic Signs, THE JOURNAL, Dec 2, 1944, p 808) describes a technic submitted to him by Dr A W Abts in a personal communication Disclaiming any intention to establish a prior use, or of any attempt to claim credit for devising the technic, I do put forth the simple statement that during my service in World War I, while on duty as a medical officer at Peter Bent Brigham Hospital, Boston, in 1918 and later at the Base Hospital at Camp Devens, Mass, I worked out a technic identical with that described by Dr Keegan, the only variation being that with the knee fully flexed on the thigh and the thigh fully flexed on abdomen, instead of forcible and quick extension at this juncture of the procedure, a torsion movement of the knee is executed toward the opposite shoulder with both shoulders resting firmly on the table At this point, or after this torsion maneuver has been executed two or three times to the point of tolerance of pain, a forcible extension is done with the full cooperation of the patient, who kicks out while the operator pulls on the ankle The same procedure is carried out on the opposite side I have used this technic continuously in private practice since that time for twenty-seven years It has, with few exceptions, proved to be a valuable manipulation In a small percentage of cases sufficient relaxation has not been possible without an anesthetic, and even with sodium pentothal the procedure is still a simple one and is a manpower hour saver, for the patients are sent right back to work Furthermore, the relief experienced after the procedure keeps these patients out of the physical therapy department, thereby conserving man hours and prevents many from becoming 'body conscious" It certainly is true that it is much easier to rub disease into the back than to rub it out of the mind Orthopedic men have been slow to recognize the role of the nucleus pulposus in low back pain As a matter of fact orthopedic surgeons in many instances have "high browed" the suggestion of manipulation on the acutely strained back and are reluctant to go beyond the usual measures employed in acute low back pain, such as heat, massage and strapping Dr Keegan's series of 243 cases of herniation of the nucleus with 115 verified by operation should do much to emphasize and clarify the foggy conception that has so long existed in the profession concerning low back pains

The flexion-torsion maneuver, I believe, not only has a tendency to increase the disk width posteriorly but widens the disk laterally as well, and, as Dr Keegan has shown, the herniation is not directly against the posterior ligament but slightly laterally in the narrow angle of the canal against a special lateral portion of the ligamentum flavum, for which Dr Keegan suggests the name interarticular ligament

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Placenta Delivered Five Hours Before Birth of Fetus. R. Torpin.—p. 436.

Fetus Adipocere Monster. J. J. Gill.—p. 440.

Cervical Carcinoma and Pregnancy.—Kobak and his associates have seen 8 cases of concurrent cervical carcinoma and pregnancy during the last five years at the Cook County Hospital in Chicago. The youngest of the patients was 25, the oldest 43 years of age. In 7 patients the growth was a stratified squamous cell carcinoma and in 1 patient it was an adenocarcinoma. There is a tendency to regard carcinoma of the cervix during pregnancy as so improbable that other causes of bleeding are given precedence in diagnosis and therapy. The growth is thus diagnosed more often toward the end of pregnancy when it has achieved large proportions. Carcinoma of the cervix develops at a rapid pace during pregnancy. The treatment depends on the disposition of the pregnancy. In the first trimester the pregnancy is disregarded and high voltage x-ray therapy is instituted. With the death of the fetus, radium is added to the treatment. In advanced pregnancy the cervix should be spared the injuries that occur during parturition. If there is no infection a classic cesarean section is performed to prevent cervical trauma and to leave intact the fundal portion of the uterus to facilitate radium therapy, which is started after uterine involution has occurred. A total of 4,500 mg. hours of radium is given in three equally divided doses. As soon after the delivery of the baby as possible, high voltage x-ray treatments are started and are continued for a long time. In the presence of local infection a Porro cesarean section is preferred. In pregnancies close to viability the cesarean section may be deferred, and 1,500 to 3,000 mg. hours of radium may be given to the cervix to inhibit temporarily the progress of the new growth. The ultimate prognosis for the patient depends on the persistent continuation of the high voltage x-ray and radium therapy that is instituted after the disposition of the pregnancy.

Androgenic Therapy in Malignant Disease of Female Genitalia.—Abel directs attention to the difficulty of selecting patients for treatment with androgen because to withhold for experimental purposes any of the accepted modes of treatment to patients with early carcinoma was unjustified. Endocrine therapy had to be reserved for those patients who failed to respond to orthodox forms of treatment and for whom it was felt that nothing more could be accomplished. From 140 to 150 mg. of testosterone propionate was given by mouth every week (two 10 mg. tablets daily) or the patients were given three 50 mg. injections a week intramuscularly. The first 5 patients, including 3 with carcinoma of the cervix and 2 with carcinoma of the corpus, have been receiving testosterone propionate for ten months. Symptomatically these patients have been definitely improved. A feeling of well being, improved morale, control of menopausal symptoms and increased libido have all been regularly observed. No regression or even retardation of the malignant process was noted.

Critical Analysis of Twenty-Two Years' Experience with Cesarean Section. R. A. Johnston.—p. 576.

Prolapse of Urethra Treated by Hepburn Operation. J. R. Miller.—p. 591.

Wertheim Operation for Cervical Carcinoma.—Sixty-five patients form the basis for this report. Patients selected for the operation should be young, preferably below 50 years of age and in good physical condition. Obese women should not be chosen. The tumor may involve the cervix in part or entirely; it may advance on the vaginal walls to not over 1 cm. from the cervix. The cervix should be movable, as felt by vagina and by rectum; fixation must mean infiltration beyond the cervix, and, although the lesion can be removed, lymphatics full of cancer cells cannot. Palpation of lymph nodes in the iliac, ureteral or obturator regions is no excuse for not operating if the other reasons for selection are satisfactory. It is exactly in such cases that there is hope for cure by means of radical surgery. The operation is the classic Wertheim or Clark operation, which involves a complete dissection of the pelvic lymph nodes from the bifurcation of the aorta down, plus the removal of the cervix, vagina and parametrium. Meigs prefers to call this operation the Wertheim-Clark plus the Taussig operation. The only really serious and annoying complication is damage to the ureter and consequent ureterovaginal

fistula. There was no postoperative mortality. Five of the 65 patients are known to be dead and in 3 of the 5 the lymph nodes had become involved. Of the 53 patients who were free from lymph node involvement only 2 have died. Surgical removal of early cervical cancer is as safe as radiation treatment. The number of fistulas of the ureterovaginal type is still too large, but with a better understanding of the blood supply fewer such calamities are expected. Lymph node involvement is curable by surgery.

*Necrotizing Bronchopneumonia: Its Relation to Radiation Therapy of Cancer of Oral Cavity. L. V. Ackerman, H. M. Wiley and D. V. LeMone.—p. 281.

Necrotizing Bronchopneumonia.—Ackerman and his associates maintain that necrotizing bronchopneumonia and necrotizing suppurative bronchopneumonia are more descriptive and accurate terms than aspiration pneumonia. Necrosis of the bronchial walls and suppuration of the lung parenchyma supplied by the involved bronchus or bronchi are invariably present. The distribution is lobular and localized to one or more bronchopulmonary segments. Patients with cancer of the oral cavity are likely to develop this complication, particularly if the lesion interferes with deglutition. The authors present observations on 14 patients with necrotizing pneumonia. Three had primary carcinoma of the tongue, 2 of the lip, 3 of the buccal mucosa, 5 of the larynx and 1 of the gum. Twelve of these patients died after completion of treatment, the shortest time interval before death being three days and the longest period eleven months. The 2 remaining patients, whose clinical symptoms and x-ray findings strongly suggest necrotizing bronchopneumonia, are well. Necrotizing pneumonia can occur during, immediately after or relatively late after radiotherapy to cancer of the oral cavity and larynx. The clinical symptoms and signs are typical. A high pulse rate with a relatively low grade fever is of particular significance. The x-ray appearance is characteristic and the differential diagnosis is not difficult, provided adequate knowledge of the historical and clinical aspects is available. The most important preventive measure is carefully planned roentgen therapy, with particular attention to divided dose technic, selection of fields and adequate filtration. If necrotizing bronchopneumonia is diagnosed early roentgen therapy may be effective, but in late cases no treatment will be of value.

*Air Embolism in Obstetrics and Gynecology. W. F. Finn.—p. 100.

Air Embolism Following Tubal Insufflation.—A woman aged 28 was admitted for tubal insufflation because of sterility of four years' duration. On the twenty-first day of the menstrual cycle she was anesthetized with nitrous oxide and ether. After the uterine cavity had been sounded at 9 cm., passage of gas at 80 to 100 mm. was heard on two occasions. Curettage was performed and 0.5 cc. of tissue grossly characteristic of secretory endometrium was obtained. About twenty minutes after the start of the operation the patient had difficulty in breathing. Respirations had ceased and only a feeble carotid pulse could be obtained. Resuscitation and stimulants were used without avail. Necropsy revealed a patent left tube, stenosis in the outer third of the right tube and 25 cc. of air in the right ventricle and pulmonary arteries. Finn reviews 4 similar cases of fatal air embolism following tubal insufflation which had been reported before and stresses that, because of the danger of air embolism, tubal insufflation should not be performed in the premenstrual phase, nor should a curettage be done simultaneously.

Treatment of Clinical Shock with Gelatin.—Evans and Rafel used gelatin in the treatment of 67 patients who were in shock because of trauma to the extremities, chest and abdomen, and of 28 severely burned patients. Gelatin for intravenous use is prepared by hydrolysis; if certain precautions are observed, a product of rather unusual uniformity as regards viscosity and molecular homogeneity can be obtained. Studies have made it clear that for intravenous use not "any" gelatin solution will suffice. Tourtelotte supplied the authors with two types of gelatin solution, the "lightly" and the "heavily degraded." The heavily degraded gelatin leaves the blood rapidly, while most of the lightly degraded gelatin is still present in the blood stream at the eighth hour after rapid infusion. Only by the "rapid syringe technic" have the authors

found it possible to restore rapidly and adequately the circulating blood volume of many severely shocked patients. Blood volume determinations and hematocrit estimations were made on many patients. That shock was due mainly to the decreased circulating blood volume was borne out by these laboratory investigations and also by the recovery of large quantities of whole blood in many of the patients operated on. Experience with gelatin in the management of burn shock has been very satisfactory. The present plan of management is to reserve its use for the first twenty-eight to forty-eight hour period, when burn shock is most to be feared, and then give whole blood.

Intra-Abdominal Use of Heparin.—Lehman and Boys found that best results are obtained by administering heparin at the close of an abdominal operation and by paracentesis every twelve hours for three days. Massie used this method with a slightly modified technic in 7 cases. After the first operating room dose he gives 10,000 units every twelve hours until a total of 40,000 units has been given. The postoperative course was stormy in most of the cases. Intra-abdominal heparin to prevent obstructing adhesions should be limited to patients who have had one or more operations for obstruction or repeated attacks following abdominal surgery. The hazards are hemorrhage, infection and possibly delay in wound healing. The contraindications to its use are recent abdominal surgery, incomplete hemostasis and intestinal resection. The hazards should be recognized promptly and can be checked by blood transfusion. Red cell and hemoglobin determinations, blood pressure reading and the general appearance of the patient are better guides than coagulation time tests. Accidental opening of the bowel during the dissection of adhesions is not a contraindication for heparin administration. In this small series there has been complete absence of obstruction in the months and years following the use of heparin in the abdomen.

Therapy of Tularemia.—Bell and Kahn administered the following therapeutic agents to guinea pigs infected with tularemia: sulfanilamide, sulfadiazine, sulfamerazine, acriflavine, metaphen, iodide and bismuth (iodobismitol with saligenin), arsenic and bismuth (solution of bismuth subgallate and sodium para-aminophenyl arsonate), trivalent arsenic alone (oxophenarsine hydrochloride), antimony (stibophen), penicillin and hyperimmune equine antitularemic serum. These drugs were used in amounts which proportionately exceeded the doses given human patients. Therapeutic trials did not demonstrate any advantage in employing these drugs.

Relapsing Plasmodium Vivax Malaria in Soldiers from South Pacific.—Gordon and his associates describe the clinical features of relapsing Plasmodium vivax malaria in 435 soldiers evacuated to the United States from the South Pacific area. During observation at Harmon General Hospital a total of 421 clinical attacks occurred in 295 or 68 per cent of the 435 patients. Of the 139 patients with no attacks, 47 had been observed for only one month. Chills were frequent; in only 12 per cent was there neither chill nor chilly feeling. There were headache, backache and generalized aches, malaise and weakness, nausea and vomiting, herpes labialis and cerebral symptoms. The spleen and liver could be palpated in 23 and 11 per cent respectively. In 313 attacks treated solely with quinacrine, fever subsided promptly. The effect of quinacrine hydrochloride on the incidence of positive malarial smears was studied in 200 patients. All patients had positive smears before treatment was started. On the fourth day after quinacrine had been started only 1 per cent still had positive smears. The great efficacy of quinacrine in controlling symptoms and fever is thus a reflection of its effect on parasitemia. All except one of the attacks observed were due to P. vivax. The need for a program of rehabilitation became obvious. A majority of the patients had somatic complaints for which no definite organic cause could be found. There is evidence that the rate of relapse of malaria decreases as time goes on.

Occlusion of Hepatic Veins.—According to Kelsey and Comfort the records of all cases in which necropsy was done at the Mayo Clinic from 1910 to 1939 inclusive has disclosed 20 cases of occlusion of the hepatic veins. In 16 cases the occlusion was an incidental finding at necropsy and had not produced recognizable symptoms. In 4 cases it had caused symptoms, and in 3 of these it had contributed to or been the chief cause of death. The occlusion was in all cases due to thrombosis. Thrombosis of the hepatic veins is not so rare that it can be dismissed entirely as a diagnostic possibility. In the chronic forms of the disease the progressive course, in some cases punctuated by acute episodes, the relatively rapid increase in the size of the tender liver and the severe epigastric pain extending to the thoracic or the lumbar region should arouse suspicion that some unusual condition, such as thrombosis of the hepatic veins rather than cirrhosis or carcinoma of the liver, is the cause of the symptoms. Peritoneoscopy may eventually serve to distinguish the congested liver of obstruction of the hepatic veins from the cirrhotic or carcinomatous liver. Hepatosplenomegaly in a case in which evidence of thrombosis of the inferior vena cava has been present will suggest extension of the thrombosis to the hepatic veins. Examination of the direction of the flow of blood in the collateral circulation will aid in the differentiation of obstruction of the hepatic veins and obstruction of the inferior vena cava. An upward flow indicates obstruction of the inferior vena cava, a downward flow obstruction of the hepatic veins. In cases of more acute occlusion of the hepatic veins as well as in the acute terminal episodes of the chronic form of the disease the rapidity of increase in the size of the liver together with evidence of profound disturbances of hepatic function and of portal obstruction that could be caused only by some rapidly developing process, such as thrombosis, may well suggest the correct diagnosis. Acute occlusion has been confused with acute pancreatitis, but elevation of values for serum amylase as well as rapid enlargement of the liver and rapid development of portal obstruction should materially aid in distinguishing the two conditions.

Edema of Lower Extremities Complicating Prefrontal Lobotomy.—Two of the older patients among 19 on whom prefrontal lobotomy had been performed died of pneumoni while convalescing from the operation Still another had acut

collapse of a lung soon after the lobotomy but recovered. Immediately after operation all had rectal and vesical incontinence. Ten of the 17 survivors continue to have occasional sphincter accidents. Postoperative observations on these 17 patients revealed that 8 had complications referable to the legs and feet, mostly edema associated with tenderness. In some patients bullae developed about the heels at areas most vulnerable to pressure. Ziegler and Osgood emphasize that alteration of the vascular supply of the brain may be responsible for the functional impairment of structures at a considerable distance from the vascular defect. The anterior cerebral artery courses backward over the mesial surface of the brain, sending branches laterally, upward and posteriorly to supply the gray and white matter of a narrow volume of the cerebrum adjacent to the mesial surface, as far back as the parieto-occipital sulcus. Some branches of the anterior cerebral artery supply the anterior portion of the thalamus, the basal ganglions and a part of the internal capsule. Small branches of the anterior cerebral artery might suffer interruption by the lobotomy, with consequent damage to cortical association fibers and even the cortex itself. The anterior cerebral artery and its possible anomalies deserve renewed investigation. Milroy's disease (familial hereditary edema) and other obscure edemas of the feet and legs, as well as bullae, may be found to have a causative factor in the central nervous system, and it may well be discovered that enuresis is more than a defective habit.

Herpes Simplex Keratitis in Malaria.—Chamberlain and Bronson encountered among troops who have contracted malaria in tropical combat areas numerous instances of keratitis due to herpes simplex virus. These infections have frequently resulted in serious scarring of the cornea, and the ulcers have been prone to recur with successive attacks of malaria. Plasmodium vivax was demonstrated in blood smears from 13 patients who had keratitis associated with herpes simplex and who had been exposed to malaria. In each patient the onset of corneal ulceration followed shortly after an acute malarial recurrence. The incidence of dendritic keratitis in the malaria group was 1 in each 188 new patients examined in the ophthalmologic clinic, whereas among patients not exposed to malaria the incidence was 1 in each 1,100 new patients. Corneal infection associated with herpes simplex would seem to be about six times as frequent among troops infected with malaria. Sulfadiazine powder applied locally to 5 dendritic ulcers promoted rapid healing in each instance. In 4 cases of atypical recurrent herpetic ulcers sulfadiazine was of no demonstrable benefit. Results suggest that sulfadiazine may prove a satisfactory adjunct to the accepted treatment of dendritic keratitis with strong solution of iodine U. S. P. Local applications of sulfanilamide were of no value. From the cornea of each of 2 patients with recurrent malarial attacks and dendritic keratitis the causative agent was transferred to a rabbit's cornea and thence to the chorioallantoic membrane of a chick embryo, where characteristic lesions of herpes simplex virus were produced. The identity of the virus was confirmed by neutralization tests. When the skin was tested for sensitivity to herpes simplex antigen, positive responses were obtained in about 80 per cent of a sample of hospitalized adult patients, and there was no appreciable difference in incidence between malarial and nonmalarial patients. Thirteen patients with herpes simplex keratitis were shown by neutralization tests to have serum antibodies against a known strain of herpes simplex virus. Each of these patients gave a strongly positive cutaneous reaction to the herpes simplex antigen.

Transplantation of Epiphysial Cartilage.—A boy now 11 years old was injured when at the age of 3 years some one stepped on his foot with a high heel. Cellulitis developed and operation revealed osteomyelitis of the first metatarsal bone. In response to the Orr treatment the patient rallied, but extreme shortening of the large toe and pronation of the foot resulted. Four years later epiphysial cartilage from a fibula, containing a portion of diaphysis, was successfully transplanted to the first metatarsal bone. The toe, which was greatly shortened prior to operation, was immediately corrected by the transplant. Observations made over approximately three years show that the transplant has taken and is functioning physiologically. The metatarsal bone in the foot which was operated on is of exactly the same size as the bone in the opposite foot. The proximal portion of the epiphysis appears to have fused with the cuneiform bone without impairing the growth of bone, which takes place more distally. Wenger cannot prophesy the eventual fate of the transplant at this time, but the extremely gratifying results obtained to date give assurance that this procedure is valuable.

Blocking of Middle Cervical and Stellate Ganglions.—Pereira blocks the middle cervical and stellate ganglions by an anterior approach. This method has the following advantages: 1. It is devoid of the risk of vascular and pleuropulmonary accidents. 2. It has a deep point of osseous reference, easy to identify by palpation of the transverse process of the sixth cervical vertebra. 3. The maximum effect is produced by blocking not only the stellate ganglion but the intermediate and the middle cervical ganglion. He arrived at obtaining without accidents a block of the middle cervical, intermediate and stellate ganglions by descending infiltration anesthesia of these ganglions, with the needle inserted at the level of the base of the anterior surface of the transverse process of the sixth cervical vertebra. If the anesthetic does not diffuse downward suffi-

ciently to block completely the stellate ganglion, the needle must be inserted a second time and directed to the base of the transverse process of the seventh cervical vertebra, and the anesthetic must be injected close to the intermediate ganglion and the vertebral artery. In this manner one can obtain a safe block of the middle cervical, intermediate and stellate ganglions.

*Diverse Clinical Picture of Coronary Heart Disease. L. R. Levy.—p. 171.
Treatment of Coronary Disease. C. C. Wolferth.—p. 185.
*Use of Concentrated Human Serum γ-Globulin in Prevention and Attenuation of Measles. C. A. Janeway.—p. 202.

Coronary Heart Disease.—Levy stresses the diversity of manifestations of coronary heart disease. There may be minimal symptoms and pronounced changes in the form of the electrocardiogram. In the presence of advanced coronary sclerosis a severe emotional strain can induce acute coronary insufficiency and so cause sudden death. The electrocardiogram may be normal less than twenty-four hours before fatal coronary occlusion. There may be striking serial changes in the electrocardiogram indicating closure of coronary arteries in a patient who is ambulatory, active and entirely free from cardiac discomfort. When the symptoms are puzzling and the examination, including the electrocardiogram, reveals no signs of heart disease, the anoxemia test is often useful in affording graphic evidence of a diminished coronary reserve. This consists in permitting the patient to breathe a mixture of 10 per cent oxygen and 90 per cent nitrogen for twenty minutes or until cardiac pain appears. A control electrocardiogram is taken and records are made at intervals of five minutes while the patient breathes the low oxygen mixture. Measurement of these records shows in patients with a diminished coronary reserve characteristic changes which are not observed when the coronary blood flow is adequate.

Concentrated Human Serum Gamma Globulin in Measles.—Janeway demonstrated that concentrated human serum gamma globulin derived from blood collected by the American Red Cross contains a twenty-five-fold concentration of most of the antibodies present in normal adult serum. This makes it possible to give the equivalent of 125 cc. of pooled adult serum in a single intramuscular injection of 5 cc. This material is now being distributed by the American Red Cross, through public health agencies, for the prevention and modification of measles, a purpose for which it has been proved particularly effective and safe. When administered in the first six days after exposure to measles, a dose of 0.08 to 0.1 cc. per pound will give protection to 3 out of 4 persons, with mild measles in the fourth, while a dose of one fourth this much, or 0.02 to 0.025 cc. per pound, will result in an attack of mild measles in most cases. In a large series of cases, very few reactions to intramuscular injection of the globulin have been observed, and these have been mild and chiefly local. The complication rate in modified measles appears to be definitely lower than in the typical disease.

Contact Poison Plants in Old World Tropics. E. D. Merrill.—p. 115.

Air Blast Injury.—Brubaker reports observations on 15 patients suffering from the percussive effects of high explosives. In 3 patients pain and hyperesthesia were presumably due to a traumatic peripheral neuritis of the supraorbital nerve. Injection of the supraorbital nerve with procaine produced complete although transient relief. Two patients had hypersensitiveness of the skin of root distribution. In cases with supraorbital pain and hyperesthesia it is possible that the nerve was contused at its exit from the supraorbital canal. In the treatment of critical pulmonary blast injuries strict bed rest and limitation of motion are necessary. Plasma is rarely indicated for the accompanying shock because increase in the intravascular hydrostatic pressure resulting from the introduction of plasma augments the outpour of fluid and thus hastens death. The chief problem is to tide the patient over the acute transudative phase of the injury by preventing loss of circulating fluid into the lungs. This might be accomplished by exhalation against positive pressure as provided by a type of intermittent flow mask such as that designed by Barach. It is possible that such pressure on exhalation might stem the transudation of fluid into the alveoli in blast injury, thus preventing the anoxia resulting from the loss of absorptive surface and, at the same time, the shock secondary to the diminution of circulating fluid. Measurement of the depth of foxholes and their distance from the bomb craters suggested that a hole rendering the maximum protection from blast should be about 4 feet deep. Men in shallow foxholes have been killed outright, while others in the same radius protected by holes 4 to 5 feet deep escaped injury. A hole much deeper than this involves the risk of suffocation from collapse.

Second Attack of Poliomyelitis.—A woman at the age of 32, in October 1942, developed a second attack of poliomyelitis, having had a first attack thirteen years previously at the age of 18. The first attack, which had developed after intimate contact with a sister who had a paralytic attack of poliomyelitis, had left the patient with wasting and flabbiness of the calf muscles of the right leg but with little loss of function. The patient walked with a slight limp. During the second attack, examination revealed a partial paralysis of both legs and weakness of the lumbar muscles. Wyllie reports that treatment with the Kenny packs was begun on the day of admission and continued daily for twenty-five days. On her discharge from the hospital there was some loss of power in the extensor muscles of the right thigh and loss of power in the left thigh muscles but improvement in the muscles of the lumbar region.

Papaverine in Disease of Coronary Arteries.—Gray and his associates present the results of objective studies on the use of papaverine in the treatment of 13 patients with angina pectoris who made weekly visits to the angina clinic of the Beth Israel Hospital. Papaverine hydrochloride appears to have a definite but limited and temporary vasodilator action in patients with coronary artery disease. The administration of this drug intravenously enabled half the patients with angina pectoris to do more work than was possible otherwise and decreased the electrocardiographic changes following exercise. This effect reached its maximum in five to fifteen minutes after injection and was negligible after about sixty minutes. This therapy is of little value in the clinical treatment of patients with angina pectoris. The oral administration of papaverine hydrochloride in doses of 33, 100 or 200 mg. to ambulatory patients did not improve their ability to exercise and does not appear to be of practical value in the treatment of angina pectoris. Studies on a small group of patients suggest that the administration of papaverine hydrochloride intravenously in doses of 65 or 100 mg. is of considerable value in treating the pain of coronary occlusion or coronary failure.

Trench Foot and Immersion Foot.—White and Scoville state that trench foot and immersion foot are similar clinical entities that differ from frostbite in the type of exposure and the reaction of the tissues and their method of recovery. Three stages are described: the initial response to cold, short of actual freezing of the tissue cells, the early period of recovery, characterized by painful hyperemia, and the residual effects of fibrosis. The initial treatment is similar to that for burns but should include cooling to reduce the oxygen demands of the skin to a level compatible with the flow of blood through damaged subcutaneous vessels. Late treatment consists in conservative minimal amputations, exercises and physical therapy to decrease tissue fibrosis and joint stiffness and sympathectomy in selected cases with residual circulatory insufficiency. Gangrene of the toes and distal portions of the feet constitutes a serious problem in trench foot but is rare in immersion foot, in which the lower extremities are less liable to trauma and infection. Prolonged partial disability is frequent in both conditions. Improvement in protective clothing, widespread instruction in foot care and first aid and a critical evaluation of the response of the fibrosed tissues to sympathectomy are in order.

High Altitude Joint Pains.—Thomas and Williams made an x-ray study of the affected joints in a decompression chamber at altitudes of 33,000 and 38,000 feet both in the presence and in the absence of pain Lateral views of the knees were made with a small portable x-ray machine Gas can be shown in the knee joint in every person, whether with or without "bends" pain, at an altitude of about 20,000 feet increasing to a maximum in about thirty minutes at 30,000 feet Large volumes of gas (estimated at 50 to 75 cc) are clearly shown in one of the reproduced roentgenograms Gas in the knee joint is not necessarily associated with pain and may be freely aspirated It consists of nitrogen, oxygen and carbon dioxide approximately in equilibrium with the normal blood gases It appears also in periarticular tissues in small irregular collections, in small discrete bubbles and in streaks along fascial planes and tendons The gas is usually reabsorbed from the soft tissues and joint spaces by the time sea level is reached although small (2 mm) bubbles persist in a few instances for as long as five minutes after return to sea level

Blood Pressure and Hypertension in Toxemias of Pregnancy.—Barnes and Browne analyzed the blood pressure of 1,956 women. Of these 915 were nulliparous and 1,041 were parous. There were no statistically significant differences between the mean level of blood pressure in nulliparous and in parous women at any age. There was no significant difference between the percentages of nulliparous and parous women with blood pressures over 120/80 or over 140/90. The number of pregnancies had no demonstrable effect on the mean level of blood pressure in parous women. Pregnancy does not cause chronic hypertension. Pregnancy does not aggravate a tendency to hypertension, nor does chronic hypertension develop earlier in parous women. Though hypertension is a common remote sequel of toxemia of pregnancy, it is not caused by the toxemia. A tendency to hypertension often contributes to the severity of toxemia. Toxemia of pregnancy may be regarded as a temporary disorder leaving no permanent lesion. There is therefore no justification for terminating a toxemic pregnancy prematurely in order to protect the mother from chronic hypertension. There is no evidence that pregnancy permanently aggravates hypertension already existing when pregnancy starts. There is therefore no justification for terminating an early pregnancy in a patient with essential hypertension.

Minimal Weight Standard for Viable Premature Infants.—Henderson regards it as unfortunate that a minimal weight standard for viable premature infants was not adopted concurrently with the maximal weight standard of 5½ pounds (2.5 Kg.). The relation of the birth weight and the estimated period of gestation in 1,041 liveborn premature infants (twins excluded) has been investigated. The average weight of infants of twenty-eight weeks gestation, the age at which the fetus is generally presumed to become viable, appears to be between 3 and 3½ pounds (1.3-1.5 Kg.). A minimal arbitrary weight standard for premature infants of 2 pounds 12 ounces (1,250 Gm.) has been proposed for the following reasons: (*a*) The average weight of infants of twenty-eight weeks' gestation appears to be about 2¾ pounds. (*b*) The weight of 2¾ pounds avoirdupois corresponds to the weight of 1.25 Kg. (1,250 Gm.) in the metric system. This correspondence in round figures is an essential condition of an international standard. (*c*) The minimal weight of 2¾ pounds is exactly half of the maximal weight of 5½ pounds, a fact which simplifies the definition of the weight range of prematurity. The term "previable" has been proposed for the separate category of liveborn premature infants with a birth weight of less than 2¾ pounds. Only 4 of 118 previable infants survived.

***Riboflavin* Deficiency in Pregnancy.**—Braun and his associates designate maceration and fissuring at the lips and angles of the mouth, glossitis, seborrheic accumulations of the nasolabial folds and certain ocular manifestations as evidence of riboflavin deficiency. In Palestine riboflavin deficiency is observed with some frequency in pregnant women. In a series of 900 pregnant women studied by the authors 190, or 21 per cent, presented manifestations of riboflavin deficiency. These symptoms made their appearance almost always during the last trimester of pregnancy and regressed shortly after delivery. An etiologic relationship between these symptoms and riboflavin deficiency was established by economic and dietary investigation, the low urinary excretion of riboflavin and the favorable response to treatment with riboflavin.

*Joint Excision in Gunshot Injuries. H. von Haberer.—p. 729.
Solitary Extoses. H. Sjövall.—p. 737.

Excision of Joint in Gunshot Injuries.—Haberer feels that excision of a joint is warranted by improvement in methods of joint surgery in which shortening of the extremity may be kept within certain limits. Secondary osteomyelitis may be prevented by adequate drainage, by immobilization with extension and by avoidance of too early transportation of the wounded. The great majority of joint injuries are caused by shell fragments rather than by infantry missiles, as in the first world war, and thus the danger of infection is increased. Excision should be done in cases in which infection threatens life and in which at least partial functional capacity may be preserved. Except for injuries of the hip joint, amputation is suggested for injuries of the lower extremities in which excision would have to be very extensive so that functional capacity could not be preserved. In a similar type of injuries of the upper extremities the extremity as such should be preserved by excision of the joint.

*Observations on Undernourished Persons. K. Perakis and D. Bakalos.—p. 746.

Observations on Undernourished Persons.—Observations in the General State Hospital in Athens revealed four types of hunger edema. The cachectic type was characterized by emaciation and by slight swelling of the face and the extremities. Extreme weakness was the chief complaint and sudden death occurred regularly in the absence of prodromal signs or after diarrhea of short duration. Generalized dropsy was the second type; it was observed in less debilitated persons. Recovery occurred in the absence of intestinal disorders, and the prognosis was much more favorable in younger persons. The incidence of the third, the polyserositic, type was high. Prolonged ascites was observed frequently, but recovery occurred regularly although reaccumulation of fluid took place after evacuation. The serous fluid was deficient in albumin (2.25 per cent to 5.50 per cent). The presence of chyle associated with fatty globules was observed in 2 cases. Prognosis was less favorable in cases in which all the serous cavities were involved. The fourth type with localized edema of the face and of the extremities was characterized by a mild clinical course. Gastrointestinal disorders played an important part. Dilatation of the stomach was frequently present together with hypoacidity of the gastric juice. Diarrhea with ten to thirty movements daily was considered to be an unfavorable symptom. Stools containing undigested food, mucus, blood and pus were observed in the grave cases in which extensive ulceration of the mucous membrane of the colon was demonstrated at necropsy. Polyuria and excessive excretion of sodium chloride, bradycardia and hypotension were common. Capillary alterations in cachectic patients resulted in formation of a vascular nevus on the back of the hand and on the face. Frostbite caused by cold alone has not been observed in Athens heretofore but did result from the combined effect of cold and undernourishment. Nervous disorders with loss of tendon reflexes and of vesical and rectal control were frequent. Epithelial and subepithelial polymorphous keratitis were frequently

present. A protracted hyperglycemic course was revealed by the blood sugar curve. There was a pronounced increase in the diastase values of the blood serum. A balanced diet was not available, but young people recovered on a diet which consisted of 30 Gm. of olive oil, 90 Gm. of bread and 180 Gm. of legumes (lentils, peas and beans). Fifty cases of pellagra occurred, but the nonmalignant course of the disease is emphasized. No other diseases due to vitamin deficiency were observed.

*Serous Radiculoneuromyelitis. W. Ederle.—p. 773.
Observations on Typhus. Heimberger.—p. 775.

Serous Radiculoneuromyelitis.—Generalized motor paresis with paresthesia, especially in the distal parts of the extremities, are to be considered a uniform neuritic symptom of a group of diseases. Secondary postdiphtheritic polyneuritis is a typical representative of this group, but the same clinical course may be observed after localized pyogenous infection or after gastrointestinal disorders. Serous inflammation of the nerve roots, the spinal cord and the peripheral nerves was the basis of 23 cases reported by Ederle. The collective term "serous radiculoneuromyelitis" is suggested for this group of cases, which presented an increase in the protein in the cerebrospinal fluid without corresponding increase in cells (Guillain-Barré type). There was considerable edema about the spinal cord, particularly of the meninges and the spinal ganglions. Only 1 of the author's patients died; 22 recovered within two to three months. Malarial therapy is contraindicated because of myocardial involvement demonstrated by electrocardiograms in half of the cases. Treatment consisted in rest in bed while paralysis was in progress. Exercises and electrotherapy were instituted during the quiescent stage. Intravenous injections daily of 100 mg. of crystalline vitamin B_1 hydrochloride and subcutaneous injections of 1 ampule of acetylcholine were given.

Therapy of Diphtheria.—Hess reports results of treatment of diphtheria with serum and homeopathic drugs. Of 1,045 patients with diphtheria who were treated only with serum during the period from 1925 to 1942 71 (6.4 per cent) died. From Dec. 1, 1941 to Nov. 30, 1942 318 of 503 patients with diphtheria were treated only with serum, while 185 were given serum and homeopathic drugs; 12 (3.7 per cent) of the patients treated with serum died; 20 (10.8 per cent) of the patients given the combined treatment died. There were more toxic cases among those treated with serum and homeopathic drugs, but the total mortality rate of the 503 patients was 6.3 per cent, almost the same as the mortality rate of 6.4 per cent of the 1,045 patients treated only with serum. The good results claimed by the homeopaths from combined therapy were not proved. The administration of homeopathic drugs in addition to serum is ineffective in toxic cases of diphtheria as well as in uncomplicated cases in which serum therapy was instituted too late or in insufficient doses. Early administration of serum (at least 500 immunizing units per kilogram of body weight) intravenously (in fractional doses twice a day) and continued intramuscularly until the false membrane disappears is highly recommended. Shock from intravenous injections of serum and blood transfusions, or rise of temperature and chill produces changes in the organism which may have a good effect on the course of diphtheria. An abscess may be produced by subcutaneous injection of turpentine in addition to intensive serum therapy to divert the defense power of the organism to a different localization and to relieve the heart in toxic cases. Recovery resulted from this combined treatment in 12 of 13 cases and only 1 case proved fatal. The patients were between the ages of 2½ and 57 years.

Gastric Regions and Anti-Pernicious Anemia Principle of Liver.—To determine where and how the anti-pernicious anemia principle is formed, Petri and his associates performed resections of various parts of the stomach on hogs. Previous investigations revealed that total resection of the fundus leads to complete disappearance of the anti-pernicious anemia principle of the liver. However, nicotinic acid administration subsequent to total resection of the fundus compensates this loss of the active principle. This compensation depends on the presence of the cardia and on parenteral administration of nicotinic acid.

Ulcerative Colitis After X-Ray Treatment of Uterine Cancer.—Engelbreth-Holm reports the histories of 4 patients in whom radium and roentgen treatment of cervical carcinoma was followed by severe colitis with purulent diarrhea and fever. The disease took a rapid course, and all 4 patients died after from nine to thirty days.

*Cerebral Disturbances in Angioneurotic Edema. Estrid Ottesen.—p. 487.

Cerebral Disturbances in Angioneurotic Edema.—Ottesen reports a case of angioneurotic edema associated with convulsions in a man aged 41. The family history was negative as to epilepsy and other nervous and mental disorders and for allergic disease. At the age of 10 the patient suffered from urticaria and at 17 he fell from a height of about 35 feet and injured the left side of his head. The injury produced only mild symptoms and no subsequent discomfort. Six weeks prior to his admission to the hospital he had suffered from a sudden generalized attack of tonic-clonic convulsions accompanied by unconsciousness. He subsequently suffered from three similar attacks, one of which affected only the left side. During the patient's stay in the hospital there was noted the typical angioneurotic edema of the lower lip, the tongue, the right cheek, the right foot, the prepuce and the dorsum of the penis. Diagnosis of angioneurotic encephalopathy was made. Literature records 7 cases of angioneurotic edema associated with convulsions. In 22 additional cases from the literature a number of other symptoms of neurologic interest were described, such as transitory exophthalmos, oculomotor paresis, aphasia, hemipareses of apoplectiform character, symptoms of increased intracranial pressure and choked disk. The etiology of angioneurotic edema is associated with disturbances of the vegetative nervous system, allergy and heredity. The prognosis is good in the nonhereditary cases. The possibility of angioneurotic edema should be kept in mind when one is faced with an obscure morbid condition associated with cerebral manifestations.

Book Notices

Operations of General Surgery. By Thomas G. Orr, M. D., Professor of Surgery, University of Kansas School of Medicine, Kansas City, Kansas. Cloth. Price, $10. Pp. 723, with 570 illustrations. Philadelphia & London: W. B. Saunders Company, 1944.

A surgical generation ago a book on operative surgery was the chief preceptor of the physician who desired to expand his activities into operative therapy. This demand for didactic instruction in technical procedures was filled by many books dealing with this subject, some of which presented the surgical technic of the time in a manner complete and historically correct but without selective guidance. Since then surgery has become more specialized, based as it is on new developments, but it has also become more critical of operative procedures, as the result of the study of end results and of the application of basic medical sciences to diseases treated by operative measures. The interest of surgeons has been directed to the more general aspects of preparing patients for operation and to treating and preventing complications of the operation. This expansion of surgical interest has been of major importance to the betterment of surgical results but may have led us too far away from the technics which, while not of sole importance, must always be of a high fixed quality in any operation. Dr. Orr has rendered a real service in bringing up to date the technics of operative procedures, presenting them anew in the light of surgical advance in the past decade. The book covers, with careful selection, the technics of operations on all parts of the body except the eye, the nose and the throat. Those who specialize in the fields of neurologic, gynecologic, thoracic or genitourinary surgery may find that the presentation of the operative technics in these fields is inadequate for those who limit their endeavors to these fields, but to the surgeon who may be called on to treat the sick without benefit of consultations with specialists the presentation in these special fields will be extremely helpful. As Dr. Orr states, "students of surgery should be familiar with the standard operation of all fields of surgery."

There are twenty-one chapters arranged according to systems rather than to specialty. The first three chapters deal satisfactorily with the wound and the factors that influence healing and the details of its management. In the presentation of each system and in the discussion of the parts of these systems, the subject is approached by a general consideration of the problem, followed by a summation of a philosophical nature that clarifies and enunciates the objectives. In all situations where anatomic facts are pertinent to operative procedures, a description of the anatomy involved is given. Before each description of operative technic there is given with detail the dangers encountered during this operation and the safeguards that should be observed to minimize them.

The clinical indications for each operation are given simply and clearly. The steps of the operation are given in the same manner, with critical comments from the personal experience of the author, with pertinent additions from surgical literature that combine to give the presentation a human and very readable quality. Following each chapter is a list of references to surgical work on the topic under discussion. The illustrations are profuse, clear and instructive. Many are original and others are selected from the literature, and all have been reproduced in such size and detail that they supplement well and amplify the written text. The artists are to be complimented on their contributions to the usefulness of the book. The minor parts of technics such as dressings and the management of drains and sutures are given in detail that is of help to even the neophytes in surgery. The book is of an agreeable and satisfying format, holdable and readable. It will prove a boon to the young surgeon for whom it was actually written, to be used during his training period and immediately afterward, but it should be in the working library of every general surgeon, especially if he works without benefit of numerous consultants in surgical specialties. To all others who are interested in the technics of present day surgery the book is heartily recommended. The teachers of surgery owe to Dr. Orr a debt of gratitude for his compilation of operative technics streamlined to the practice of the present day.

Anatomy as a Basis for Medical and Dental Practice. By Donald Mainland, M.B., Ch.B., D.Sc., Professor of Anatomy, Dalhousie University, Halifax, N. S. Cloth. Price, $7.50. Pp. 863, with 61 illustrations. New York & London: Paul B. Hoeber, Inc., 1945.

The amount of time allotted to gross anatomy in the curriculum of medical schools has been reduced, because other preclinical sciences have required increased time owing to their great development during the twentieth century. Some teachers in these other sciences have felt that the time given to dissection was wasted; but most faculties feel that "menders of the human body" should trouble to know that body thoroughly, and state laws require dissection. But the anatomists have revised their courses, reducing the content considerably, though sometimes wondering if the facts of biochemistry, newly introduced, are really more important than those of anatomy which they have displaced.

Further, the anatomists have produced new books as substitutes for the old textbooks and dissecting manuals. Mainland's is one of the best of these new books. It is called simply "Anatomy," being neither a textbook (storehouse) nor a dissecting guide. It is a general educational guide for the student starting the study of human anatomy and so starting the study of medicine or dentistry. The first twenty-eight pages prepare his mind for the study of medicine, the next forty-one for the study of anatomy and the next eighty-six for dissection by a systematic consideration of the tissues of the body—of their general structure, of what they do and something of how they do it. Such an introduction to dissection has been practiced by W. E. L. G. Clark of Oxford and by many American teachers of anatomy. Five hundred and ninety-two pages are devoted to regional study of the body, and after that follow appendixes and references—ninety pages, and index—twenty-four pages.

Features of the book which seem open to criticism are the amount of attention given to statistics and statistical methods, necessary for physical anthropologists but not for medical students, and the unvarying requirement that findings in the cadaver be transferred to and marked on living bodies at once. Living models would be all dirtied up in the dissecting rooms. Instead, thorough students will doubtless make groups and study anatomy on one another at home. Some students will question both the accuracy and the logic of some answers given by the author to his own questions; but at least such students will think.

Features especially commendable are the references to recent anatomic literature, which are the best in any handbook on gross anatomy, and the questions (three hundred and thirty-seven of them) asked throughout the book and answered in one of the appendixes at the back. Good teachers make students animated interrogation points. Many facts impossible to remember are conveniently tabulated at the back, e. g. age of appearance and of fusion of ossification centers.

Each part of the book is excellent. The plan and treatment are largely original and are evidently the result of long experience by a capable and conscientious teacher. The student who works conscientiously under its guidance will become a good doctor and a good thinker. He will spend a lot of work on anatomy—every good student always will; he will not have found this book a "shorter" anatomy. Indeed, he will probably have acquired in addition to this book one of the old textbooks (for frequent reference) and an atlas (as a constant companion) and, unless the teacher prefers to give directions orally, he will also have a dissecting guide. Nevertheless, this book is one of the best guides ever written for learning the practical anatomy useful to practitioners.

Pre-Excitation, a Cardiac Abnormality: Patho-Physiological, Patho-Anatomical and Clinical Studies of an Excitatory Spread Phenomenon Bearing upon the Problem of the WPW (Wolff, Parkinson and White) Electrocardiogram and Paroxysmal Tachycardia. By Richard F. Ohnell. Acta medica Scandinavica, Supplement No. 152. Translated by Ulla Schott. Paper. Pp. 167, with 29 illustrations. Stockholm, 1944.

This monograph, a supplement to *Acta medica Scandinavica*, is an excellent translation, by Ulla Schött, of the author's views regarding the WPW syndrome. The report of 70 carefully studied cases with correlated discussion of 250 from the literature reveals his comprehensive knowledge. Since 1930 forty theories have been advanced, fifteen of these since 1940. The term preexcitation indicates an additional excitatory spread in the ventricles of the heart, coupled to the auricular excitation,

wave; the phenomenon being represented graphically by a short PR interval and a prolonged aberrant QRS complex. The author reports a case with muscle bundle connection of the left auricle and ventricle. A right sided auriculoventricular junction has been reported. Hence such an anomaly could result from the excitation wave being transmitted via both the normal and accessory conduction pathways. He gives reasons for assuming an acquired as well as a congenital etiology in these cases. He reports observations suggesting the possibility of a hereditary factor. He thinks that mechanical stimulation of an excitable ventricular focus by auricular systole or vice versa seems likely. This monograph presents the latest and most complete information.

The Treatment of Peptic Ulcer Based upon Ten Years' Experience at the New York Hospital. By George J. Heuer, M.D., Professor of Surgery of Cornell University Medical College and Surgeon-in-Chief of the New York Hospital. Assisted by Cranston Holman, M.D., Assistant Professor of Clinical Surgery, Cornell University Medical College, New York, and William A. Cooper, M.D., Assistant Professor of Clinical Surgery, Cornell University Medical College. Fabrikoid. Price, $3. Pp. 118, Philadelphia, London & Montreal: J. B. Lippincott Company, 1944.
